## Definitions

#### Definition

 $\bar{x}$  is an **equilibrium** of the equation

$$x_{n+1} = f(x_n), n = 0, 1, \dots$$

#### if

 $\bar{x} = f(\bar{x}).$ 

The correpsonding solution  $\{\bar{x}_n\}$  such that

$$\bar{x}_n = \bar{x}$$

is called also a **constant solution** or **steady-state solution**. Also, in such cases we say that  $\bar{x}$  is a **fixed point** of the function *f*.

Necessary Definitions Necessary Theorems

## Definitions

#### Definition

(Stability) (i) The equilibrium point  $\bar{x}$  of Eq. (2) is called **(locally)** stable if for every  $\epsilon > 0$  there exists  $\delta > 0$  such that

$$|x_0 - \bar{x}| < \delta$$
 implies  $|x_n - \bar{x}| < \epsilon$  for  $n \ge 0$ .

Otherwise, the equilibrium  $\bar{x}$  is called **unstable**. (ii) The equilibrium point  $\bar{x}$  of Eq. (2) is called **(locally) asymptotically stable** (LAS) if it is stable and there exists  $\gamma$ such that

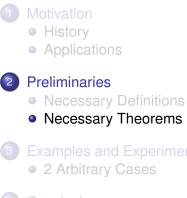

$$|x_0 - \bar{x}| < \gamma$$
 implies  $\lim_{n \to \infty} |x_n - \bar{x}| = 0.$

2 Arbitrary Cases

## Set Up

In order to better understand the difference equation

$$x_{n+1}=x_n^{\delta}e^{r-x_n},$$

we represent the model with the function

$$f(x)=x^{\delta}e^{r-x}.$$

We can use this function to better solve for equilibria and analyze stability.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへの

Motivation Preliminaries Examples and Experimentations Conclusion Finding Equilibria

In order to solve for equilibria of our equation, we must set the function f(x) = x. So

$$x^{\delta}e^{r-x}=x$$

$$x^{\delta}e^{r-x}-x=0$$

$$x(x^{\delta-1}e^{r-x}-1)=0$$

So an equilibrium exists at x = 0 and for the solution(s) of the equation  $x^{\delta-1}e^{r-x} - 1 = 0$ .

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶

2 Arbitrary Cases

## Establishing $\bar{x}$

$$x^{\delta-1}e^{r-x}-1=0$$

$$\Rightarrow 0 = x^{1-\delta} - e^{r-x} = g(x)$$

We know that

 $x \in [0,\infty).$ 

$$g(0) = -e^r$$

$$\lim_{x\to\infty}g(x)=\infty$$

 $\Leftrightarrow g(x) = 0$  has at least one solution on  $(0, \infty)$  by the IVT.

2 Arbitrary Cases

#### Establishing $\bar{x}$

We can now use g'(x) to analyze the behavior of g(x) on  $[0,\infty)$ .

$$g'(x) = (1-\delta)x^{-\delta} + e^{r-x}$$

Since  $\delta > 0, r > 0$ ,

 $g'(x) > 0, \forall x \in (0,\infty),$ 

 $\Leftrightarrow g(x) \uparrow \text{on } (0,\infty),$ 

 $\Leftrightarrow$  g(x) has exactly one solution  $\bar{x}$ .

<ロ> <同> <同> < 回> < 回> < 回> < 回</p>

2 Arbitrary Cases

## **Stability Analysis**

So f(x) has exactly two equilibria when  $0 < \delta \le 1$ Recall the following theorem

#### Theorem

An equilibrium  $\hat{x}$  of the difference equation  $x_{n+1} = f(x_n)$ : (1) is Locally Asymptotically Stable (LAS) if  $|f'(\hat{x})| < 1$ . (2) is Unstable if  $|f'(\hat{x})| > 1$ . (3) if  $|f'(\hat{x})| = 1$ , stability is inconclusive.

We can use these properties to analyze the stability at both equilibria  $x = 0, \bar{x}$ .

2 Arbitrary Cases

#### Stability of Equilibria

$$f(x) = x^{\delta} e^{r-x}$$

$$f'(x) = x^{\delta-1} e^{r-x} (\delta - x)$$

Through analysis, we find that

$$|f'(0)| > 1 \Rightarrow 0$$
 is unstable,

And we find that

$$|f'(\bar{x})| < 1 \forall r < (\delta+1) - (\delta-1)\ln(\delta+1)$$

## First we will look at some graphs of f(x) with $\delta = 2$ and various values of r

2 Arbitrary Cases

One positive equilibrium

# First we will look at some graphs of f(x) with $\delta = 2$ and various values of r

2 Arbitrary Cases

No Positive Equilibria

2 Arbitrary Cases

This leads to the following theorem:

#### Theorem

Consider Ricker's Model where  $\delta > 1, r > 0$ . The following statement is true: (a) If  $r > (\delta - 1)(1 - \ln(\delta - 1))$  it has three equilibria, the 0 equilibrium and two positive equilibria  $\tilde{x} < \delta - 1 < \bar{x}$ .

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへの

2 Arbitrary Cases

#### Proof

To prove this, we need to look at the equation

$$f(x)=x^{\delta}e^{r-x}.$$

Let us examine

$$x^{\delta}e^{r-x}=x.$$

x = 0 is always a fixed point for f, so for x > 0 we have:

$$1 = x^{\delta - 1} e^{r - x}$$
  

$$0 = 1 - x^{\delta - 1} e^{r - x}$$

Now let  $g(x) = 1 - x^{\delta-1} e^{r-x}$ . The zeroes of g(x) are the same as the positive fixed points of f(x).

2 Arbitrary Cases

## Proof

To prove this, we need to look at the equation

$$f(x)=x^{\delta}e^{r-x}.$$

Let us examine

$$x^{\delta}e^{r-x}=x.$$

x = 0 is always a fixed point for *f*, so for x > 0 we have:

$$\begin{array}{rcl}
1 & = & x^{\delta - 1} e^{r - x} \\
0 & = & 1 - x^{\delta - 1} e^{r - x}
\end{array}$$

Now let  $g(x) = 1 - x^{\delta-1}e^{r-x}$ . The zeroes of g(x) are the same as the positive fixed points of f(x).

2 Arbitrary Cases

## Proof

To prove this, we need to look at the equation

$$f(x)=x^{\delta}e^{r-x}.$$

Let us examine

$$x^{\delta}e^{r-x}=x.$$

x = 0 is always a fixed point for f, so for x > 0 we have:

$$\begin{array}{rcl}
1 & = & x^{\delta - 1} e^{r - x} \\
0 & = & 1 - x^{\delta - 1} e^{r - x}
\end{array}$$

Now let  $g(x) = 1 - x^{\delta-1}e^{r-x}$ . The zeroes of g(x) are the same as the positive fixed points of f(x).

2 Arbitrary Cases

From this graph of g(x) with  $\delta = 2$  and r = 1.5, we can observe that g(x) has two positive equilibria in this case. We have

$$g'(x) = x^{\delta-2}e^{r-x}(x-(\delta-1)),$$

and g'(x) = 0 if  $x = \delta - 1$ , so the minimum of g is less than 0 if  $g(\delta - 1) < 0$ . This is true if  $r > (\delta - 1)(1 - \ln(\delta - 1))$  as stated, thus completes this proof.

◆□ → ◆□ → ◆ □ → ◆ □ → ◆ □ → ◆ ○ ◆

2 Arbitrary Cases

#### Theorem

Consider the difference equation (1) where  $\delta > 1$  and

$$(\delta-1)(1-\ln(\delta-1)) < r \leq (\delta+1)-(\delta-1)\ln(\delta+1).$$

Then the positive equilibrium  $\bar{x} > \delta - 1$  is LAS.

We demonstrate this theorem setting  $\delta = 2$  and using varying values of *r* and initial conditions  $x_0$ . Note that when  $\delta = 2$ , the theorem states that  $\bar{x}$  is LAS for  $1 < r \le 3 - \ln 3 \approx 1.90$ .

#### Theorem

Consider the difference equation (1) where  $\delta > 1$  and

 $(\delta - 1)(1 - \ln(\delta - 1)) < r \le \delta - (\delta - 1)\ln(\delta).$ 

Let  $\tilde{x}, \bar{x}$  ( $\tilde{x} < \delta - 1 < \bar{x}$ ) be two positive equilibria of the same equation, and  $\hat{x} \neq \tilde{x}$ , satisfies  $f(\hat{x}) = \tilde{x}$ . Then the basin of attraction of the positive equilibrium  $\bar{x}$  is the interval ( $\tilde{x}, \hat{x}$ ).

We will again demonstrate this theorem setting  $\delta = 2$ , r = 1.2, and using varying initial values  $x_0$ . For reference,  $\tilde{x} \approx 0.493$ ,  $\bar{x} \approx 1.77$ , and  $\hat{x} \approx 5.21$ .

## Conclusion

#### By studying Ricker's model, we have found two scenarios.

- When δ >1 for x<sub>0</sub> < x̃, the least positive equilibria, the sequence {x<sub>n</sub>} converges to zero.
- ② When  $\delta \le 1$ , two equilibria. x = 0 is an unstable equilibrium. The second equilibrium  $x = \overline{x}$  is sometimes stable.

#### Outlook

- British Petroleum Oil Leak affecting the ecosystem in the Gulf of Mexico
- The Chernobyl Nuclear Meltdown in 1986 still affecting wildlife in the Ukraine.

By studying Ricker's model, we have found two scenarios.

- When δ >1 for x<sub>0</sub> < x̃, the least positive equilibria, the sequence {x<sub>n</sub>} converges to zero.
- 2 When  $\delta \le 1$ , two equilibria. x = 0 is an unstable equilibrium. The second equilibrium  $x = \overline{x}$  is sometimes stable.
  - Outlook
    - British Petroleum Oil Leak affecting the ecosystem in the Gulf of Mexico
    - The Chernobyl Nuclear Meltdown in 1986 still affecting wildlife in the Ukraine.
