WKB ANALYSIS IN THE SEMICLASSICAL LIMIT OF
A DISCRETE NLS SYSTEM

STEPHEN P. SHIPMAN*

Abstract. The linear spectral problem associated with the inverse solution of a
finite discrete nonlinear Schrödinger chain is studied in the semiclassical limit. The
discrete spectral problem is a recursion relation for a vector quantity, with boundary
conditions, depending on initial data and a spectral parameter. WKB analysis is per-
formed and then interpreted for the case that the quantities in the chain are less than
one in modulus. In this case, the spectrum lies on the unit circle and an asymptotic
density is obtained. The density is supported by known facts about the discrete spec-
tra, numerical results, and rigorous results concerning the asymptotics of the solution
of the spectral boundary-value problem. In addition, the norming constants in the spectral
transform are positive in this special case, and a proposed asymptotic norming exponent
is corroborated by numerical data.

1. Introduction. This article examines the spectral transform asso-
ciated with an inverse solution of a finite defocusing discrete nonlinear
Schrödinger (DNLS) system of ordinary differential equations in the semi-
classical limit. The problem possesses a dichotomy of behavior depending
on initial data characterized by the unitarity or non-unitarity of the linear
spectral problem. Formal, rigorous, and numerical results lead to an un-
derstanding of the asymptotics of the unitary case. The non-unitary case
is not addressed and is as yet not understood. In the unitary case, the
spectrum of eigenvalues lies on the unit circle of the complex plane, and in
the semiclassical limit, the dimension of the linear problem is unbounded
and we seek an asymptotic density of eigenvalues. Naïve WKB analysis
leads to a candidate for this density, which is then confirmed by numerical
calculations, comparison with properties of the spectrum of the discrete
problem, and rigorous asymptotics of the unitary eigenvalue problem. In
addition, the proposed density has been applied successfully in [S] to the
study of the semiclassical limit of the solution of the DNLS system. In
the WKB analysis, the discrete index in the system of ODEs approaches
a continuous variable and the typical intervals of "oscillatory" and "expo-
nential" behavior of the solution arise. The density, as usual, involves an
integral over an oscillatory interval. A candidate for the asymptotics of
the associated norming constant has been proposed in [S] in light of analy-
ysis there of the semiclassical limit of the inverse spectral solution. The
candidate, as is typical in such asymptotic problems, involves an integral
over the exponential intervals for a special class of data, and it was chosen
to provide the correct results in that analysis. It is not understood how
it may arise directly from asymptotic analysis. In this article, however, it
is corroborated by numerical results and by comparison with properties of
the norming constant for the discrete system.

*Department of Mathematics, Duke University, Durham, NC 27708.
Previous work on continuum limits of discrete systems solvable by inverse methods and the asymptotic (WKB) analysis of the associated linear spectral problem includes the analysis by Deift and McLaughlin [DM] of a continuum limit of the Toda lattice. Using candidates arising from formal WKB analysis, they rigorously established the asymptotics of the solutions and the spectral density and norming constants. These results were preceded by rigorous results by Geronimo and Smith [GS] on asymptotic solutions to second-order recursion relations. Costin [C] has made rigorous the WKB results for finite-order recursion relations. Akin to the WKB analysis in this article but for the non-unitary case is the non-self-adjoint Zakharov-Shabat eigenvalue problem in the semiclassical limit studied by Bronski [B].

2. The spectral problem. The defocusing discrete nonlinear Schrödinger (DNLS) system

\[ \imath \dot{Q}_n + Q_{n-1} - 2Q_n + Q_{n+1} - |Q_n|^2 (Q_{n-1} + Q_{n+1}) = 0 \]

is transformed under the change of dependent variable \( Q_n \to \imath \dot{Q}_n e^{-2\imath t} \) into the system

\[ \imath \dot{Q}_n + (1 - |Q_n|^2) (Q_{n-1} + Q_{n+1}) = 0. \]

If one puts

\[ |Q_0(0)| = |Q_N(0)| = 1 \]

into (1), then \( Q_0 \) and \( Q_N \) are constant in time and a finite subchain becomes detached from the rest of the chain. One then has a finite system of ordinary differential equations for \( Q_1 \ldots Q_{N-1} \). This system is solvable by an inverse spectral method [V].

In the semiclassical limit of the finite system, one considers initial data of the form

\[ Q_n(0) = q(n\epsilon) \exp \left( \frac{\imath}{\epsilon} \phi(n\epsilon) \right), \]

in which \( q \) and \( \phi \) are fixed functions on the real unit interval such that \( q(0) = q(1) = 1 \) and \( \epsilon = 1/N \), and considers the limiting behavior of the modulus and phase as \( \epsilon \) tends to zero. As we will see, the WKB analysis lends itself to a meaningful interpretation with regard to the asymptotic distribution of eigenvalues in this special case. However, if the condition \( |Q_n| < 1 \) is violated, there is no satisfactory interpretation (so far). The reason for this is that the spectrum, in the case \( |Q_n| < 1 \), is constrained to the unit circle of the complex plane, whereas otherwise such a constraint is not known.

We now discuss the eigenvalue problem associated with the inverse spectral solution for the finite discrete system (1, 2). Let \( \{Q_n\}^N_{n=0} \) be
given such that $|Q_0| = |Q_N| = 1$ and normalized such that $Q_0 = 1$. Denote $Q_N$ by $\xi$:

$$\xi = Q_N, \quad |\xi| = 1.$$ 

Let $z$ be an arbitrary complex parameter, and define the matrices

$$U_n(z) = \begin{bmatrix} z & Q_n \\ Q_n & z^{-1} \end{bmatrix},$$

and the resulting “transfer matrices”

$$T_n(z) = \begin{bmatrix} \xi^2 & 0 \\ 0 & \xi^{-2} \end{bmatrix} U_N(z) \ldots U_1(z).$$

The eigenvalues in the spectral transform are the roots of the trace of $T_1$ as a function of $z$. We denote

$$J(z) = \text{tr} T_1(z).$$

Let $F(z)$ denote the upper left entry of $T_1(z)$. The coefficients in the partial-fraction decomposition of $F/J$ are the norming constants in the spectral transform. One shows that

$$J(z) = \xi^2 z^{-N} \prod_{k=1}^{N} (z^2 - z_k^2) \quad \text{(eigenvalues $z_k$)},$$

$$\frac{F(z)}{J(z)} = z^2 \sum_{k=1}^{N} \frac{W_k}{(z^2 - z_k^2)} \quad \text{(norming constants $W_k$)}.$$

In fact, the roots of $J$ are equal to the eigenvalues of the following boundary-value problem for the discrete evolution of a complex vector $\mathbf{u}_n$ in $\mathbb{C}^2$:

$$\mathbf{u}_{n+1}(z) = \mathbf{U}_n(z) \mathbf{u}_n(z); \quad \mathbf{u}_0(z) = \begin{bmatrix} z \\ 1 \end{bmatrix}, \quad \mathbf{u}_{N+1}(z) = \begin{bmatrix} 0 \\ 0 \end{bmatrix}.$$

The following proposition lists a number of facts about the spectral problem. We use the notation $f(z) := f(\bar{z}^{-1})$. Proofs are omitted.

PROPOSITION 1. **Facts on the spectral problem**

1. **On the spectrum:**
   (a) There are $2N$ eigenvalues, counting multiplicities.
   (b) The eigenvalues exist in plus-minus pairs.
   (c) If $z$ is an eigenvalue, then so is $\bar{z}^{-1}$.
   (d) If the values of $Q_n$ are all real, then the eigenvalues exist in conjugate pairs.
(c) If \( \{Q_n\}_{n=0}^N \) has spectrum \( \{\pm z_k\}_{k=1}^N \), then for any real constant \( \chi \), \( \{Q_n e^{\chi x}\}_{n=0}^N \) has spectrum \( \{\pm z_k e^{-\chi x/2}\}_{k=1}^N \).

(f) If \( |Q_n| < 1 \) for \( n = 1, \ldots, N-1 \), then \( |z_k| = 1 \) for \( k = 1, \ldots, N \) and the eigenvalues are distinct.

2. On the norming constants:

(a) \( \sum_{k=1}^N W_k = 1 \).
(b) If \( z_k^{-1} = z \) then \( W_k = W_k^{-1} \).
(c) If \( |Q_n| < 1 \) for \( n = 1, \ldots, N-1 \), then the norming constants \( W_k \) are real and positive and

\[
W_k = \frac{G_k := |F(z_k)|}{\prod_{k \neq \ell} |z_k^2 - z_\ell^2|} \quad (|Q_n| < 1).
\]

(d) If the \( Q_n \) are all real and \( z_k' = z_k \), then \( W_k' = W_k \). In particular, if \( |Q_n| < 1 \) for \( n = 1, \ldots, N-1 \), then \( W_k' = W_k > 0 \) and \( G_k' = G_k \).

(e) Using the notation in (2e), if \( \{Q_n\}_{n=0}^N \) has norming constants \( \{W_k\} \) and \( z_k' = z_k e^{-\imath \alpha / 2} \), then \( W_k' = W_k \).

(f) If \( |Q_n| < 1 \) for \( n = 1, \ldots, N-1 \) and the \( G_k \) are all equal, then the \( Q_n \) have the property that \( Q_{N-n} = \xi Q_n \).

3. The asymptotics of the spectral transform. We consider the eigenvalue condition in the semiclassical limit. The dependence on the spectral parameter will usually be suppressed. Let continuous functions \( q \) and \( \phi \) be given such that \( q \) has two continuous derivatives and \( \phi \) has three continuous derivatives and

\[
q : [0, 1] \to [0, 1], \quad 0 \leq q(x) < 1 \quad \text{for} \quad x \in (0, 1);
\]

\[
\phi : [0, 1] \to \mathbb{R}, \quad \phi(0) = 0;
\]

and put \( Q_n = q(ne) \exp(\frac{\imath \phi(ne)}{e}) \). The eigenvalue condition is (4), in which

\[
U_n = \begin{pmatrix} z & q(ne) \exp(-\frac{\imath \phi(ne)}{e}) \\ q(ne) \exp(\frac{\imath \phi(ne)}{e}) & z^{-1} \end{pmatrix}.
\]

To make the problem amenable to WKB analysis, we can remove the large exponent from \( U_n \) by means of the change of coordinates

\[
u_n = \begin{pmatrix} u_n^1 \\ u_n^2 \end{pmatrix} = \begin{pmatrix} e^{-\frac{i \phi(ne)}{2e}} u_n^1 \\ e^{\frac{i \phi(ne)}{2e}} u_n^2 \end{pmatrix}.
\]
then the vectors \( \mathbf{u}_n = \begin{bmatrix} u^1_n \\ u^2_n \end{bmatrix} \) satisfy

\[
\begin{bmatrix}
\bar{u}^1_{n+1} \\
\bar{u}^2_{n+1}
\end{bmatrix} = \tilde{U}_n
\begin{bmatrix}
u^1_n \\
u^2_n
\end{bmatrix}, \quad \tilde{U}_n = \begin{bmatrix}
ze^{\frac{i\psi_n}{\epsilon}} q_n e^{\frac{i\phi_n}{\epsilon}} \\
z^{-1}e^{-i\frac{\psi_n}{\epsilon}}
\end{bmatrix},
\]

in which \( \psi_n = \frac{\delta(n+1) - \delta(n)}{\epsilon} \) and \( q_n = q(n) \). Let \( \lambda^\pm_n \) be the eigenvalues of \( \tilde{U}_n \) and \( p^\pm_n \) corresponding eigenvectors, and set \( \theta_n = \text{arg} \frac{\lambda^+_n}{\lambda^-_n} \). Then the following expansions are valid:

\[
\begin{align*}
\tilde{U}_n &= \tilde{U}^\pm(n) \quad \text{where} \quad \tilde{U}^\pm(x) = \tilde{U}(x) + e\tilde{U}_1(x) + O(\epsilon^2), \\
\lambda^\pm_n &= \lambda^\pm(x) \quad \text{where} \quad \lambda^\pm(x) = \lambda(x) + e\lambda(x) + O(\epsilon^2), \\
\theta_n &= \theta(x) \quad \text{where} \quad \theta(x) = \theta(x) + \theta(x) + O(\epsilon^2), \\
p^\pm_n &= p^\pm(x) \quad \text{where} \quad p^\pm(x) = p(x) + e p(x) + O(\epsilon^2).
\end{align*}
\]

So the underscore signifies functions of the continuous variable \( x \). \( \lambda^\pm(x) \) and \( p^\pm(x) \) are the eigenvalues and eigenvectors of \( \tilde{U}_n \), and \( \theta(x) = \text{arg} \frac{\lambda^+_n}{\lambda^-_n} \). One sees that

\[
\tilde{U}(x) = \begin{bmatrix}
ze^{\frac{i\psi(n)}{\epsilon}} q(x)e^{\frac{i\phi(n)}{\epsilon}} \\
q(x)e^{-\frac{i\phi(n)}{2}} z^{-1}e^{-i\frac{\psi(n)}{2}}
\end{bmatrix},
\]

and, for unitary spectral values \( z = e^{i\eta} \),

\[
\lambda^\pm = \cos \left( \eta + \frac{\psi_n}{2} \right) \pm \sqrt{q^2_n - \sin^2 \left( \eta - \frac{\psi_n}{2} \right)},
\]

\[
\lambda^\pm(x,e^{i\eta}) = \cos \left( \eta + \frac{\phi(n)}{2} \right) \pm \sqrt{q^2 + \sin^2 \left( \eta - \frac{\phi(n)}{2} \right)}.
\]

### 3.1. WKB analysis

We begin the asymptotic analysis with a naive WKB approach to determine the leading-order behavior of the vector \( \begin{bmatrix} u^1_n \\ u^2_n \end{bmatrix} \). We consider the approximate problem for vectors \( \mathbf{v}_n \) given by

\[
\mathbf{v}_{n+1} = \tilde{U}(n)\mathbf{v}_n
\]

and perform leading-order WKB analysis on the components of \( \mathbf{v}_n \) with respect to the basis of eigenvectors \( p^\pm(n) \) using the ansatz

\[
\mathbf{v}_n = \exp \left( \frac{1}{\epsilon} S^+(n) \right) p^+(n) + \exp \left( \frac{1}{\epsilon} S^-(n) \right) p^-(n)
\]
in which \( S_+ \) and \( S_- \) are functions of \( x \) that are to be determined. We write \( \nu_{n+1} \) in two ways. On one hand,

\[
\nu_{n+1} = \sum_{\pm} \exp \left( \frac{1}{\epsilon} (S_{\pm}(ne) + \epsilon S'_{\pm}(ne)) + O(\epsilon) \right) \mathbf{p}^\pm(ne + \epsilon)
\]

\[
= \sum_{\pm} \exp \left( \frac{1}{\epsilon} S_{\pm}(ne) \right) \exp \left( S'_{\pm}(ne) \right) (1 + O(\epsilon)) \mathbf{p}^\pm(ne + \epsilon).
\]

On the other hand, from the evolution of \( \nu_n \),

\[
\nu_{n+1} = \sum_{\pm} \lambda^\pm(ne) \exp \left( \frac{1}{\epsilon} S_{\pm}(ne) \right) \mathbf{p}^\pm(ne)
\]

\[
= \sum_{\pm} \exp \left( \frac{1}{\epsilon} S_{\pm}(ne) \right) \lambda^\pm(ne) \left( \mathbf{p}^\pm(ne + \epsilon) + O(\epsilon) \right).
\]

(11)

Comparing the two representations of \( \nu_{n+1} \), one obtains the formal result

\[
S'_{\pm}(x) = \log(\Delta^\pm(x)), \quad \text{or} \quad S_{\pm}(x) = \int^{x} \log(\Delta^\pm(y)) \, dy.
\]

Let us consider the implications of this result in the case that \( 0 \leq g(x) < 1 \) for \( 0 < x < 1 \). By Statement (2c) of Proposition 1, this condition constrains the spectrum to the unit circle. Thus, let us put \( z = e^{i\eta} \). The ratio of the WKB components of \( \nu_n \) with respect to an eigenvector basis, which will be relevant in proposing the spectral density, is

\[
\mathcal{R}(x, \eta) = \frac{\exp \left( \frac{1}{\epsilon} S_{\pm}(x, e^{i\eta}) \right)}{\exp \left( \frac{1}{\epsilon} S_{\mp}(x, e^{i\eta}) \right)} = \exp \left[ \frac{1}{\epsilon} \int^{x} \log \frac{\lambda^+(y, e^{i\eta})}{\lambda^-(y, e^{i\eta})} \, dy \right].
\]

We make some observations about the values of \( \Delta^\pm \) and this ratio: \( \Delta^\pm \) are either both real with the same sign or complex conjugates of each other. For a given value of \( \eta \), \( x \)-regions with these different properties are separated from each other by “turning points” \( x_* \) for which \( g^2(x_*) = \sin^2 \left( \eta + \frac{\theta(x_*)}{2} \right) \). In an \( x \)-interval in which \( \Delta^\pm(x) \) are both real, we find that \( \mathcal{R}(x, \eta) \) is a real-valued function of \( x \) (plus a complex constant), and in an \( x \)-interval in which \( \Delta^\pm(x) \) are complex conjugate, \( \mathcal{R}(x, \eta) \) is a unitary complex function of \( x \) (plus complex a constant). Thus the interval [0, 1] is divided into “exponential” and “oscillatory” intervals separated by turning points, which depend on the value of \( \eta \). For generic values of \( \eta \), the \( x \)-values 0 and 1 are endpoints of exponential regions.

3.2. The spectral density. We now use the formal WKB result to propose an asymptotic distribution of eigenvalues. Letting \( [c_1, c_2] \) represent the vector \( \hat{u}_n \) with respect to the basis \( \{\mathbf{p}^\pm\} \), the boundary-value
problem (4) provides conditions on the quantities $\arg \left( \frac{C}{C_n} \right)$ at $n = 1$ and $n = N$. Since we know that the eigenvalues are unitary, the problem is to specify those values of $z$, as $z$ traverses the unit circle, for which the total increment of $\arg \left( \frac{C}{C_n} \right)$ is equal to $\arg \left( \frac{C}{C_n} \right) - \arg \left( \frac{C}{C_1} \right) + 2\pi k$ for some integer $k$. We already have the leading order behavior of $\arg \left( \frac{C}{C_1} \right)$: it is constant in an exponential region and equal to $\frac{1}{\epsilon} \int_0^1 \arg \left( \frac{\lambda^+(x)}{\Delta^-(x)} \right) \, dx$ in an oscillatory region. Thus the total increment from $n = 1$ to $n = N$ (or $x = 0$ to $x = 1$), to leading order, is $\frac{1}{\epsilon} \int_0^1 \arg \left( \frac{\lambda^+(x)}{\Delta^-(x)} \right) \, dx$ where the integrand is zero when $x$ is in an exponential region. The asymptotic condition for eigenvalues $z_k = e^{i\eta_k}$ is then

$$\frac{1}{\epsilon} \int_0^1 \arg \left( \frac{\lambda^+(x; z_k)}{\Delta^-(x; z_k)} \right) \, dx \sim 2\pi k \quad (\epsilon \to 0).$$

Using the expression (9) for the eigenvalues $\lambda^\pm(x; e^{i\eta})$, one computes $\arg \left( \frac{\lambda^+(x; e^{i\eta})}{\Delta^-(x; e^{i\eta})} \right)$ and finds that this condition becomes

$$\Psi(\eta) \sim \epsilon k \quad (\epsilon \to 0),$$

where the asymptotic spectral distribution $\Psi$ is defined by

$$\Psi(\eta) = \frac{1}{\pi} \int_0^1 \arctan \left( \frac{\text{Re} \sqrt{\sin^2 \left( \eta + \frac{\phi(x)}{2} \right) - q(x)^2}}{\cos \left( \eta + \frac{\phi(x)}{2} \right)} \right) \, dx.$$

To determine the limiting density of eigenvalues, we see that the number of eigenvalues in a $\eta$-interval on which $\Psi$ is monotonic is given asymptotically by $1/\epsilon$ times the absolute value of the increment of $\Psi$ over that interval. Thus we obtain the density

$$\rho(\eta) := \left| \Psi'(\eta) \right|

(12)

= \frac{1}{\pi} \left| \int_0^1 \text{Re} \left( \frac{\sin \left( \eta + \frac{\phi(x)}{2} \right)}{\sqrt{\sin^2 \left( \eta + \frac{\phi(x)}{2} \right) - q(x)^2}} \right) \, dx \right|, \quad 0 \leq \eta \leq 2\pi.

This means that, for any subinterval $[\eta_1, \eta_2]$ of $[0, 2\pi]$,

$$\#[\eta_1, \eta_2] \sim \frac{1}{\epsilon} \int_{\eta_1}^{\eta_2} \rho(\eta) \, d\eta \quad (\epsilon \to 0),$$

where “$\#$” indicates the number of eigenvalues in the given interval.

One can confirm that the asymptotic analogs of the spectral properties in Part 2 of Proposition 1 do hold for this proposed density.
Asymptotic analogs of Proposition 1, Part 1.

a. The number of eigenvalues should be asymptotically equal to 2/\(\epsilon\).
   This is the statement that
   \[
   \int_0^{2\pi} \rho(\eta) \, d\eta = 2.
   \]
   When \(\phi' (x)\) is taken to be constant, this is easily verified. In this case, \(\Psi(\eta)\) is increasing (resp. decreasing) when \(\sin (\eta + \frac{\phi'}{2})\) is positive (resp. negative), and one finds that its total variation is 2.

b. The asymptotic analog of the plus-minus parity is that \(\rho(\eta) = \rho(\eta + \pi)\).

d. The \(Q_{\chi}\) being real corresponds to \(\phi (x) \equiv 0\). In this case, \(\rho(-\eta) = \rho(\eta)\), which is the analog of conjugate parity of eigenvalues. Because of (b), there is then a four-fold spectral symmetry.

e. Multiplying the \(Q_{\chi}\) all by \(e^{in\chi}\) is asymptotically analogous to adding the constant \(\chi\) to \(\phi(x)\). This does indeed shift the proposed density function by \(-\chi/2\), as it should.

3.3. The asymptotic norming exponent. It can be shown that the norming constants have the following asymptotic behavior in the semiclassical limit:

\[
\lim_{\epsilon \to 0} \epsilon \log G_{k, \epsilon} = \mathcal{J}(\eta_*) \quad \text{if} \quad z_{k, \epsilon} \to e^{i\eta_*} \quad \text{as} \quad \epsilon \to 0,
\]

where \(\mathcal{J}\) is a function defined on the support of the asymptotic spectral density and is determined by \(q\) and \(\phi\). In the case that these data give rise to exactly two turning points for values of \(\eta\) in the support of the asymptotic density, a candidate for the asymptotic norming exponent \(\mathcal{J}(\eta)\) has been proposed in [S]. One shows that the turning-point condition
\[
q(x)^2 - \sin^2 \left( \eta + \frac{\phi'(x)}{2} \right) = 0
\]
is equivalent to
\[
2\eta = \alpha(x) + 2k\pi \quad \text{or} \quad 2\eta = \beta(x) + 2k\pi \quad \text{for some} \quad k
\]
where
\[
\begin{align*}
\alpha(x) &= 2 \arcsin(q(x)) - \phi'(x), \\
\beta(x) &= 2\pi - 2 \arcsin(q(x)) - \phi'(x).
\end{align*}
\]

and \(\beta(x) \geq \alpha(x)\), with equality only at 0 and 1.

The proposed form of the derivative of \(\mathcal{J}\) is
\[
\frac{d\mathcal{J}}{d\eta} = \left[ \pm \int_0^{x_-(\eta)} \pm \int_{x_+(\eta)}^1 \right] \Re \frac{\sin \left( \eta + \frac{\phi'(x)}{2} \right)}{\sqrt{\sin^2 \left( \eta + \frac{\phi'(x)}{2} \right) + q(x)^2}} \, dx,
\]
which is defined in the support of the spectral density. The ± sign is chosen as illustrated in Example 2 of Section 4. One can compare with this formula the asymptotic analogs of the properties of the norming constants in Part 3 of Proposition 1.

Asymptotic analogs of Proposition 1, Part 2.

d. The $Q_n$ being real corresponds to $\phi(x) \equiv 0$. The symmetry of the norming constant about the angle $\pi/2$ corresponds the the anti-symmetry of $dJ/d\eta$, which is confirmed in the proposed formula.

e. Multiplying the $Q_n$ all by $e^{i\eta}$ is asymptotically analogous to adding the constant $\chi$ to $\phi'(x)$, thus shifting the proposed asymptotic norming exponent by $-\chi/2$.

f. The property $Q_{n-1} = \xi Q_n$ corresponds to the symmetry of $q$ and $\phi'$ about $x = 1/2$, and one shows that the candidate for $dJ/d\eta$ is zero in this case. This corresponds to the converse of item (3f).

A natural candidate for $J(\eta)$ may be derived heuristically as follows:

$$
\frac{1}{N} \log |F(e^{i\eta})| \sim \frac{1}{N} \log \prod_{n=0}^{N} |U_n(e^{i\eta})| \sim \frac{1}{N} \log \max_{n=0}^{N} |\lambda_{n}(e^{i\eta})| \\
\sim \frac{1}{N} \sum_{n=0}^{N} \log \max |\lambda_{n}(e^{i\eta})| \\
\sim \int_{0}^{1} \log \max |\lambda_{n}(x, e^{i\eta})|dx = J(\eta).
$$

One finds, indeed, that this integral coincides numerically with a limiting upper envelope of the functions $\frac{1}{N} \log |F(e^{i\eta})|$. However, $\frac{1}{N} \log |F(e^{i\eta})| = \frac{1}{N} \log G_k$, from $\eta = 0$ to $\eta = \pi$, has $N-1$ spikes emanating downward from this upper envelope, and the $N$ points $(\eta_k, \frac{1}{N} \log G_k)$ lie at various places along these spikes. This is illustrated in Example 9. Thus, $\frac{1}{N} \log G_k$ is not given by $\int_{0}^{1} \log \max |\lambda_{n}(x, e^{i\eta})|dx$. Recall that $\sum_{k=1}^{N} W_k = 1$ and

$$
W_k = \prod_{k' \neq k}^{1} \frac{G_k}{|z_{k'}^2 - z_k^2|}.
$$

So $\frac{1}{N} \log G_k < \frac{1}{N} \sum_{k' \neq k} \log |z_{k'}^2 - z_k^2|$ for each $k$. If one calculates numerically the asymptotic form of the right-hand side,

$$
\frac{1}{N} \sum_{k' \neq k, k \neq N} \log |z_{k'}^2 - z_k^2| \sim \int_{0}^{\pi} \log |e^{2i\eta} - e^{2i\eta'}| \rho(\eta') d\eta' \quad (N \to \infty)
$$

if $z_{kN} \to e^{i\eta}$ as $N \to \infty$, one finds that it also coincides with the limiting upper envelope of $\frac{1}{N} \log |F(e^{i\eta})|$ (even for values outside the support of $\rho$).
4. Numerical results. The numerical calculations in Examples 1 and 2 compare the proposed asymptotic spectral density \( \rho(\eta) \) and norming exponent \( \mathfrak{J}(\eta) \) defined in (12) and (14) with actual spectral data for various choices of \( q, \phi, \) and \( N \).

5. Asymptotics of the transfer matrix. In this section, we take a rigorous approach to determining the asymptotic behavior of the transfer matrix over an oscillatory region and over an exponential region and establish some asymptotics of the solution to the linear problem. Let \([a, b]\) be an oscillatory or exponential interval for data \( q(x) \) and \( \phi(x) \) and spectral value \( \epsilon \eta_n \) whose distance from any turning point is bounded from below. Define \( \mathfrak{u} = [a/\epsilon] \) and \( \mathfrak{v} = [b/\epsilon] \), and let \([c_n^1, c_n^2]^	op\) represent the vector \( \mathfrak{u}_n(\epsilon \eta_n) \) in the eigenvector basis \( \{\mathfrak{d}_n(\epsilon \eta_n)\} \) for \( \mathfrak{U}_n(\epsilon \eta_n) \).

**Theorem 2.** Given the notation above,

1. Let \([a, b]\) be an oscillatory interval. Then, for each sufficiently small \( \epsilon > 0 \), there exists a solution \([c_n^1, c_n^2]^	op\) such that, if \( ne \in [a, b] \), then

\[
\arg \frac{c_n^1}{c_n^2} = \frac{1}{\epsilon} \int_a^{ne} \arg \frac{\lambda^+(y)}{\lambda^-(y)} \, dy + A(ne) + o(\epsilon, ne),
\]

\[
c_n^1 = (A^+(ne) + o_+(\epsilon, ne)) \exp \left( \frac{1}{\epsilon} \int_a^{ne} \lambda^+(y) \, dy \right),
\]

in which \( A(x) \) and \( A^\pm(x) \) are continuous functions depending on \( q \) and \( \phi \) and the choice of eigenvectors and

\[
o(\epsilon, x), o_+(\epsilon, x) = o(1) \quad (\epsilon \to 0),
\]

uniformly in \( x \).

2. Let \([a, b]\) be an exponential interval, and suppose that \( 0 < \lambda_n^- < \lambda_n^+ \). Then, for each sufficiently small \( \epsilon > 0 \), there exists a solution \([c_n^1, c_n^2]^	op\) such that, if \( ne \in [a, b] \), then

\[
c_n^1 = (B(ne) + o_1(\epsilon, ne)) \exp \left( \frac{1}{\epsilon} \int_a^{ne} \lambda^+(y) \, dy \right),
\]

\[
c_n^2 = o_2(\epsilon, ne) \exp \left( \frac{1}{\epsilon} \int_a^{ne} \lambda^-(y) \, dy \right),
\]

in which \( B \) is determined by \( q \) and \( \phi \) and the choice of eigenvectors and depends continuously on its arguments and

\[
o_1, o_2(\epsilon, x) = o(1) \quad (\epsilon \to 0),
\]

uniformly in \( x \).
Example 1. This is an example in which $\psi$ is not constant so that the spectral density has no symmetries. The value of the density changes abruptly at the values of $\eta$ that separate regions with two turning points from those with four. The approximate density for $1/\epsilon = 750$ was obtained using 10 eigenvalues per density point. Two observations about the $\eta$-interval with four turning points: The three points where the upper and lower envelopes for the irregularly placed values of the approximate density come together coincide with the graph of the proposed asymptotic density. Using more eigenvalues per density point decreased the deviation from the asymptotic density.
Example 2. \( f' \) is symmetric about \( \pi/2 \). This is because, if \( q \) and \( \phi \) are symmetric about \( x = 1/2 \), then \( f' \) is symmetric about \( \eta = \pi/2 \), and the shifting up of \( \phi' \) by \( 1/2 \) produces the shift to the left of the spectral data by half of that. The bottom graph above illustrates several things. The lower string of circles shows the values of \( \frac{1}{N} \log |F(e^{i\eta})| \) (black line) evaluated at the eigenvalues \( \eta_k \) for \( N = 16 \). Such data is difficult to obtain for large values of \( N \) because of the sensitivity of \( F \) to changes in \( \eta \) on the spikes. For very large values of \( N \), however, an upper envelope for \( \frac{1}{N} \log |F(e^{i\eta})| \) can still be calculated, and the limiting values of this envelope as \( N \to \infty \) is represented by the grey curve. Also coinciding with the grey curve are the two asymptotic quantities discussed in Subsection 3.3—\( \int_0^\pi \log \max|\lambda^\pm(x,e^{i\eta})|dx \) and \( \int_0^\pi \log|e^{2i\eta} - e^{2i\eta}|d\eta \). The upper string of circles are the quantities \( \sum_{k' \neq k} \log |x_k^2 - x_{k'}^2| \) plotted against \( \eta_k \).
5.1. Preliminaries. Let $\hat{U}_n$ be the matrix taking $\begin{bmatrix} c_1^n & c_2^n \end{bmatrix}^t$ to $\begin{bmatrix} c_{n+1}^1 & c_{n+1}^2 \end{bmatrix}^t$. Then $\hat{U}_n = M_n \Lambda_n$ where $\Lambda_n = \text{diag}(\lambda_1^n, \lambda_2^n)$ and $M_n$ is the change-of-basis matrix from $\{p_1^n, p_2^n\}$ to $\{p_{n+1}^1, p_{n+1}^2\}$. Assuming three continuous derivatives of $\phi$ and two of $q$, and using the expansions (6), one computes that $M_n = I + \epsilon R_n$ where the entries $r_{ij}^k$ of $R_n$ have the property that, for some differentiable functions $\xi_{ij}^k$ of $x$, $|r_{ij}^k - \xi_{ij}^k(\epsilon)| = O(\epsilon)$ uniformly in $x \in [a, b]$. This means that $r_{ij}^k = \xi_{ij}^k(\epsilon)$ for some functions $\xi_{ij}^k$ of $x$ such that $\xi_{ij}^k(x) = \xi_{ij}^k(x) + O(\epsilon)$ as $\epsilon \to 0$ uniformly in $x$. We will study the asymptotic behavior of the transfer matrix $T^\epsilon$ taking $\begin{bmatrix} c_1^n & c_2^n \end{bmatrix}$ to $\begin{bmatrix} c_{n+1}^1 & c_{n+1}^2 \end{bmatrix}$:

$$T^\epsilon := \prod_{n=\underline{n}}^{\bar{n}} \hat{U}_n = \prod_{n=\underline{n}}^{\bar{n}} (I + \epsilon R_n) \Lambda_n.$$

The multiplication is ordered, factors with a lower index being to the right of factors with a higher index. We will study the case in which $[a, b]$ is contained in an oscillatory $x$-region and the case in which it is contained in an exponential region. We begin the analysis by bringing this expression for $T^\epsilon$ into a form in which its structure and limiting behavior is more transparent. Expanding in powers of $\epsilon$, $T^\epsilon$ takes the form

$$T^\epsilon = \sum_{\ell=0}^{\bar{L}} \epsilon^{\ell} T_\ell$$

where $\bar{L} = \bar{n} - \underline{n} + 1$ and

$$T_\ell := \sum_{\underline{n} \leq n_1 < \ldots < n_\ell \leq \bar{n}} \left( \prod_{n=n_\ell+1}^{n_1} \Lambda_n \right) R_{n_\ell} \left( \prod_{n=n_\ell+1}^{n_\ell+1} \Lambda_n \right) \ldots \left( \prod_{n=n_1+1}^{n_2} \Lambda_n \right) R_{n_2} \left( \prod_{n=n_2+1}^{n_1} \Lambda_n \right) \ldots \left( \prod_{n=\underline{n}+1}^{\bar{n}} \Lambda_n \right)$$

and $T_0 := \prod_{n=\underline{n}}^{\bar{n}} \Lambda_n$. One can bring out a factor on the right, common to each $T_\ell$, by using the following formula recursively: For any $i \leq n' \leq j$,

$$\left( \prod_{n=n'+1}^{j} \Lambda_n \right) R_{n'} \left( \prod_{n=i}^{n'} \Lambda_n \right) = \begin{bmatrix} r_{n'}^{1j} & \epsilon r_{n'}^{12} \frac{j}{n'_{n'_{n'-1}+1}} \frac{\lambda_1^n}{\lambda_2^n} & \cdots & \epsilon r_{n'}^{12} \frac{j}{n'_{n'_{n'-1}+1}} \frac{\lambda_2^n}{\lambda_2^n} \\ r_{n'}^{2j} & \epsilon r_{n'}^{22} \frac{j}{n'_{n'_{n'-1}+1}} \frac{\lambda_1^n}{\lambda_2^n} & \cdots & \epsilon r_{n'}^{22} \frac{j}{n'_{n'_{n'-1}+1}} \frac{\lambda_2^n}{\lambda_2^n} \end{bmatrix} \left( \prod_{n=i}^{n'_n} \Lambda_n \right) \left( \prod_{n=n'+1}^{j} \Lambda_n \right).$$

Setting first $(i, n', j)$ equal to $(n_{\ell-1} + 1, n_{\ell}, \bar{n})$, then $(n_{\ell-2} + 1, n_{\ell-1}, \bar{n})$, and so on up to $(\underline{n}, n_1, \bar{n})$, we arrive at the following expression for $T_\ell$:
\[ T_\ell = \left( \sum_{\mu \leq n_1 < \ldots < n_\ell \leq n} \hat{R}_{n_\mu} \cdots \hat{R}_{n_\ell} \hat{R}_{n_1} \right) \prod_{n=\overline{2}}^{n} \Lambda_n \]

in which

\[
\hat{R}_{n'} := \begin{bmatrix}
    r^{11}_{n'} & r^{12}_{n'} \prod_{n=n'+1}^{\infty} \frac{\lambda^+}{\lambda^*_n} \\
    r^{21}_{n'} \prod_{n=n'+1}^{\infty} \frac{\lambda^-}{\lambda^*_n} & r^{22}_{n'}
\end{bmatrix}
\]

Using the notation

\[ P_\ell := \sum_{\mu \leq n_1 < \ldots < n_\ell \leq n} \hat{R}_{n_\mu} \cdots \hat{R}_{n_1}, \]

we can write

\[ T_\ell = P_\ell \prod_{n=\overline{2}}^{n} \Lambda_n \]

to obtain the form

\[ T^c = \left( \sum_{\ell=0}^{L} e^\ell P_\ell \right) \prod_{n=\overline{2}}^{n} \Lambda_n. \]

One computes the products \( \hat{R}_{n_\mu} \cdots \hat{R}_{n_1} \) (the sums are over \( n \)):

\[ \hat{R}_{n_2} \hat{R}_{n_1} = \begin{bmatrix}
    r^{11}_{n_2} r^{11}_{n_1} + r^{12}_{n_2} r^{21}_{n_1} \prod_{n_2+1}^{n_1} \frac{\lambda^+}{\lambda^*_n} & r^{11}_{n_2} r^{12}_{n_1} \prod_{n_2+1}^{\infty} \frac{\lambda^+}{\lambda^*_n} + r^{12}_{n_2} r^{22}_{n_1} \prod_{n_2+1}^{\infty} \frac{\lambda^-}{\lambda^*_n} \\
    r^{21}_{n_2} r^{11}_{n_1} \prod_{n_2+1}^{\infty} \frac{\lambda^-}{\lambda^*_n} + r^{22}_{n_2} r^{21}_{n_1} \prod_{n_2+1}^{\infty} \frac{\lambda^-}{\lambda^*_n} & r^{22}_{n_2} r^{22}_{n_1}
\end{bmatrix}, \]

and the first column of \( \hat{R}_{n_3} \hat{R}_{n_2} \hat{R}_{n_1} \) is

\[ \begin{bmatrix}
    r^{11}_{n_3} r^{11}_{n_2} r^{11}_{n_1} + r^{12}_{n_3} r^{21}_{n_2} r^{11}_{n_1} \prod_{n_3+1}^{n_2} \frac{\lambda^+}{\lambda^*_n} + r^{11}_{n_3} r^{12}_{n_2} r^{21}_{n_1} \prod_{n_3+1}^{n_2} \frac{\lambda^+}{\lambda^*_n} + r^{12}_{n_3} r^{22}_{n_2} r^{21}_{n_1} \prod_{n_3+1}^{n_2} \frac{\lambda^-}{\lambda^*_n} + r^{12}_{n_3} r^{22}_{n_2} r^{22}_{n_1} \prod_{n_3+1}^{n_2} \frac{\lambda^-}{\lambda^*_n}
\end{bmatrix}. \]

Inductively, we find that \( \hat{R}_{n_\mu} \cdots \hat{R}_{n_1} \) includes the terms \( r^{11}_{n_\mu} \cdots r^{11}_{n_1} \) and \( r^{22}_{n_\mu} \cdots r^{22}_{n_1} \) in the upper left and lower right entries, respectively. The rest of the terms all contain factors that are products of the form \( \prod_{n=\overline{1}}^{n+1} \frac{\lambda^+}{\lambda^*_n} \).

In the first column, \( \lambda^*_n \) always appears in the numerator, and in the second
column, \( \lambda_n^+ \) always appears in the numerator. We find then that \( P_\ell \) has the form

\[
P_\ell = \begin{bmatrix}
\sum_{n \leq m_1 < \cdots < m_\ell \leq \bar{n}} r_{n_1}^{11} \cdots r_{m_1}^{11} & 0 \\
0 & \sum_{n \leq m_1 < \cdots < m_\ell \leq \bar{n}} r_{n_1}^{22} \cdots r_{m_1}^{22}
\end{bmatrix}
\]

(15)

\[+ \sum_{n \leq m_1 < \cdots < m_\ell \leq \bar{n}} \begin{bmatrix}
(2^{\ell-1}-1) \text{ terms} & 2^{\ell-1} \text{ terms} \\
2^{\ell-1} \text{ terms} & (2^{\ell-1}-1) \text{ terms}
\end{bmatrix}
\]

(\( R_0 \) is the identity matrix) where the "terms" are as described above.

By induction on \( \ell \), one can prove the following Lemma on the structure of the first column of \( \hat{R}_{n_\ell} \cdots \hat{R}_{n_1} \) and a similar lemma for the second column. \( \hat{R}_{n_\ell} \cdots \hat{R}_{n_1} \) is assumed to be in simplified form in the sense that factors of the form \( \frac{\lambda_n^+}{\lambda_n^-} \frac{\lambda_n^-}{\lambda_n^+} \) are removed.

**Lemma 3.** on the first column of \( \hat{R}_{n_\ell} \cdots \hat{R}_{n_1} \).

1. The first entry contains the term \( r_{n_1}^{11} \cdots r_{m_1}^{11} \) and \( 2^{\ell-1}-1 \) terms with factors of the form \( \prod_{n=m_1+1}^m \frac{\lambda_n^-}{\lambda_n^+} \) for \( m_1, m_2 \in \{n_1, \ldots, n_\ell\} \) (not the empty product). These factors have the following properties:
   a. For any \( n \), the factor \( \frac{\lambda_n^-}{\lambda_n^+} \) occurs with multiplicity at most 1.
   b. For one factor, \( m_2 = n_\ell \).

2. The second entry contains \( 2^{\ell-1} \) terms with factors of the form \( \prod_{n=m_1+1}^m \frac{\lambda_n^-}{\lambda_n^+} \) for \( m_1, m_2 \in \{n_1, \ldots, n_\ell, \bar{n}\} \) (not the empty product). These factors have the following properties:
   a. For any \( n \), the factor \( \frac{\lambda_n^-}{\lambda_n^+} \) occurs with multiplicity at most 1.
   b. For one factor, \( m_2 = \bar{n} \).

**5.2. Oscillatory region.** Let us now consider the case in which \([a,b]\) is contained in an oscillatory region. The goal is to show that, as \( \epsilon \) tends to zero, the transfer matrix is asymptotic to a diagonal matrix that depends only on \( q \) and \( \phi \), times \( \prod_{n=\bar{n}-\ell}^{n_1} \Lambda_n \). The task is to show that, by letting \( \epsilon \) tend to zero, one can bring the expansion \( \sum_{\ell=0}^{\infty} \epsilon^\ell P_\ell \) into any vicinity of a fixed diagonal matrix. Whereas \( P_0 \) is just the identity matrix, it is not obvious that the \( \epsilon^1 \)-term

\[
\epsilon P_1 = \epsilon \sum_{n \leq m_1 < \cdots < m_\ell < \bar{n}} \begin{bmatrix}
r_{n_1}^{11} & r_{m_1}^{12} & \prod_{n=m_1+1}^m \frac{\lambda_n^-}{\lambda_n^+}
\end{bmatrix}
\]

\[
= \begin{bmatrix}
r_{n_1}^{11} & \prod_{n=m_1+1}^m \frac{\lambda_n^-}{\lambda_n^+} & r_{m_1}^{22}
\end{bmatrix}
\]

for example, is tending to a diagonal form. One expects the diagonal entries to converge to the integrals $\int_0^b \xi^a(x) dx$ if the functions $q$ and $\phi$ are sufficiently smooth. One can apply a naive formal argument to the other entries by replacing the product in, say, the $(1, 2)$-entry by its asymptotic form $\exp \left( i \frac{1}{\epsilon} \int_0^b \xi^a(x') dx' \right)$ and replacing the sum by an integral:

$$
\epsilon \sum_{0 \leq n_1 \leq \pi} r_{n_1}^{1/2} \prod_{n=n_1+1}^{n_{h+1}} \lambda_n^{\pm} \rightarrow \int_a^b \xi^{1/2}(x) \exp \left( i \frac{1}{\epsilon} \int_a^b \xi(x') dx' \right) dx.
$$

This formal limit does indeed tend to zero, however, converting what is essentially a Riemann sum into an integral is not so simple because of the fast oscillations in the integrand. Indeed, the period of the oscillations is at the order of the mesh size $\epsilon$.

A similar but more complicated situation occurs in the higher-order terms in the expansion of $T^e$. In an oscillatory region, the "terms" in expression (15) for $P_\ell$ are, for some index $h$, of the form

$$(16) \quad r_{n_1} \cdots r_{n_h} \cdots r_{n_1}^{(u)} \prod_{n=n_{h+1}}^{n_{h+1}} \lambda_n^{\pm}$$

where $n_{h+1}$ may be equal to $\pi$ and $n_{h-1}$ may be equal to $2$, the asterisk (*) represents any superscript from the set $\{11, 12, 21, 22\}$, and $u$ is a product of expressions that do not depend on $n_h$ and are of the form $\prod_{n=n_1}^{n_{h+1}} \lambda_n^{\pm}$ and are therefore unitary.

Again, one expects the quantities $\epsilon^\ell \sum_{0 \leq n_1 \leq \pi} r_{n_1}^{1/2} \cdots r_{n_h}^{1/2}$ to converge to an $\ell$-fold integral over the region $a \leq x_1 < \cdots < x_\ell \leq b$. Each of the other terms is oscillating in at least one of the variables $n_h$ and, extending the technique discussed above for the case when $\ell = 1$, one can show that each of these terms converges to zero.

Now, the number of these terms grows exponentially with $\ell$, and, as $\epsilon$ decreases, the degree $L$ of the expansion of $T^e$ in $\epsilon$ increases. One can solve these problems with the observation that the number of terms in a sum over $n \leq n_1 < \cdots < n_\ell \leq \pi$ is less than $\binom{n}{\ell}$ (recall that $\epsilon = 1/N$), and, upon multiplying by $\epsilon^\ell$, one can bound the whole expansion containing the "terms" of $T^e$ by a quantity that tends to zero as $\epsilon \to 0$. The details are in the proof of Proposition 5.

In formulating the lemma, the interval $[a, b]$ must be bounded away from any turning point so that the functions $\xi^a(x)$ are bounded and the function $e^{i \xi^a(x)}$ is bounded away from the real axis. We make the following definitions:

- Let the number $\sigma$ be such that $|1 - \exp(i \xi^a(x))| > \sigma$ for $x \in [a, b]$.
- If $\xi^a$ is continuous on $[a, b]$, then $\frac{d \xi}{dx}$ is bounded on $[a, b]$, so there exists a number $K$ such that $|\xi(x_2) - \xi(x_1)| \leq K|x_2 - x_1|$ for all $x_1, x_2 \in [a, b]$. 

The difference quotients \( \frac{\phi(x+\epsilon) - \phi(x)}{\epsilon} \) converge to \( \phi'(x) \) uniformly on \([a, b]\) provided that \( \phi' \) is continuous. This implies the existence of a number \( \tau \) such that \( |\psi_n - \psi(ne)| \leq \tau \epsilon \) whenever \( ne \in [a, b] \).

One can verify that the functions \( \psi^{ij}(x) \) have continuous derivatives on \([a, b]\), and this implies the existence of a number \( \beta \) such that \( |\psi^{ij}(x_2) - \psi^{ij}(x_1)| \leq \beta |x_2 - x_1| \) for \( x_1, x_2 \in [a, b] \).

The existence of a number \( \gamma \) such that, for \( i, j \in \{1, 2\}, |\psi^{ij} - \psi^{ij}(ne)| < \gamma \epsilon \) has already been discussed.

The continuity of the functions \( \psi^{ij}(x) \) and the previous bullet imply the existence of a number \( \alpha \) such that, for \( x, ne \in [a, b] \), \( |\psi^{ij}(x)| < \alpha \) and \( |\psi^{ij}(ne)| < \alpha \).

Define \( S_i(a, b) = \int_a^b \psi^{ii}(x) \, dx \), for \( i = 1, 2 \).

The first lemma obtains estimates on the oscillating terms in \( P_\epsilon \). One must understand why the sum over \( u \leq n_1 < \cdots < n_\ell \leq N \) of any one of these terms, multiplied by \( \epsilon^{\ell_i} \), tends to zero. Let \( Y \) denote a general one of these quantities:

\[
Y := \epsilon^{\ell} \sum_{u \leq n_1 < \cdots < n_\ell \leq N} r_{n_\ell}^* \cdots r_{n_u}^* \prod_{n=n_{u+1}}^{n_{n+1}} \left( \lambda_{n}^+ \right) \lambda_{n}^-.
\]

**Lemma 4.** Let \([a, b]\) be an oscillatory interval with positive distance from the set of turning points, and let \( \rho > 0 \) be given. Then \( \epsilon' > 0 \) can be chosen sufficiently small such that whenever \( 0 < \epsilon < \epsilon' \), \( |Y| < \epsilon^{2(\alpha)\ell-1} \rho \) for any quantity of the type \( Y \).

**Proof.** Denote by \( \theta(x) \) either \( \arg \left( \frac{\lambda^+(x)}{\lambda^-}(x) \right) \) or \( \arg \left( \frac{\lambda^-(x)}{\lambda^+}(x) \right) \), and by \( \theta_n \) the corresponding quantity \( \arg \left( \frac{\lambda^+(x)}{\lambda^-}(x) \right) \). Rewrite \( Y \) as

\[
Y = \epsilon^{\ell-1} \sum_{\mu \leq n_1 < \cdots < n_\ell \leq N} r_{n_\ell}^* \cdots r_{n_u}^* \prod_{n=n_{u+1}}^{n_{n+1}} \left( \epsilon \sum_{n=n_{n+1}}^{n_{n+1}} r_{n_n}^* \exp \left( i \sum_{n=n_{n+1}}^{n_{n+1}} \theta_n \right) \right).
\]

The circumflex marks a removed factor or variable. Since \( |r_{n_\ell}^* \cdots r_{n_u}^* \prod_{n=n_{u+1}}^{n_{n+1}} \left( \epsilon \sum_{n=n_{n+1}}^{n_{n+1}} r_{n_n}^* \exp \left( i \sum_{n=n_{n+1}}^{n_{n+1}} \theta_n \right) \right)| < \alpha^{\ell-1} \) and there are no more than \( \binom{N}{\ell-1} < \frac{N^{\ell-1}}{(\ell-1)!} \) terms in the outer sum, we see that

\[
|Y| < \alpha^{\ell-1} \left( \frac{N^{\ell-1}}{(\ell-1)!} \right) \left( \max_{\mu \leq n_1 < \cdots < n_\ell \leq N} \left| \epsilon \sum_{n=n_{n+1}}^{n_{n+1}} r_{n_n}^* \exp \left( i \sum_{n=n_{n+1}}^{n_{n+1}} \theta_n \right) \right| \right).
\]

Let us study a single quantity of the type

\[
\Omega := \epsilon \sum_{n=n_{n+1}}^{n_{n+1}} r_{n_n}^* \exp \left( i \sum_{n=n_{n+1}}^{n_{n+1}} \theta_n \right).
\]
Let $\nu$ be given such that $0 < \nu \leq \frac{1}{2}$ and $\nu^{\frac{1}{2}} < \frac{1}{2}|b - x_4|$ for all turning points $x_4$, and assume that $0 < \epsilon < \nu^{\frac{1}{2}}$. Let $M$ be a positive number such that $M^{-\frac{1}{2}} < \epsilon < M^{-\frac{1}{2}} < \nu^{\frac{1}{2}}$. The following procedure applies to any one of these quantities $\Omega$. First, if $(n_{h+1} - n_{h-1} - 1)\epsilon < M^{-1}$, then it is clear that $|\delta| < \alpha M^{-1}$. Otherwise, if $(n_{h+1} - n_{h-1} - 1)\epsilon > M^{-1}$, then we divide the interval $[(n_{h-1} + 1)\epsilon, n_{h+1}\epsilon)$ into disjoint subintervals $[em_{k-1}, em_k)$, $k = 1, \ldots, K$ where $m_0 = n_{h-1} + 1$ and $m_K = n_{h+1}$, such that, if we set $M_k = m_k - m_{k-1}$ for $k = 1, \ldots, K$, then $M^{-1} < M_k \epsilon < 2M^{-1}$. The first part of this inequality implies $K < M^4$. In summary, the conditions are
\[
M^{-\frac{1}{2}} < \epsilon < M^{-\frac{1}{2}} < \nu^{\frac{1}{2}},
M^{-4} < M_k \epsilon < 2M^{-4},
K < M^4.
\]

Now break $\Omega$ into a sum

\[
\Omega = \epsilon \sum_{k=1}^{K} \Omega_k,
\]

in which

\[
\Omega_k = \sum_{m_k-1}^{m_k} r_{m_k}^* \exp \left( i \sum_{n=m_k+1}^{m_k+1} \theta_n \right).
\]

If we define $r_{m_k}^* = r_{m_k} \exp \left( i n_{m_k} \theta_n \right)$, then we can rewrite $\Omega_k$ as

\[
\Omega_k = \sum_{m_k-1}^{m_k} r_{m_k}^* \exp \left( i \sum_{n=m_k+1}^{m_k+1} \theta_n \right)
\]

and compare it with the “constant frequency and amplitude” quantity

\[
\Omega_k := \sum_{m_k-1}^{m_k} r_{m_k}^* \exp \left[ i (m_k - n_h) \theta_0(m_k \epsilon) \right].
\]

First, for any $n_h$ such that $m_{k-1} \leq n_h < m_k$,

\[
\exp \left( i \sum_{n=n_h+1}^{n_h} \theta_n \right) = \exp \left[ i (m_k - n_h) \theta_0(m_k \epsilon) \right] \exp \left( i \sum_{n=n_h+1}^{m_k} \theta_n - \theta_0(m_k \epsilon) \right)
\]

and, from the definitions of $\kappa$ and $\tau$,

\[
|\theta_n - \theta_0(m_k \epsilon)| < M_k \epsilon \kappa + \epsilon \tau
\]

whenever $m_{k-1} \leq n_h < m_k$, so we get the bound

\[
\left| \sum_{n=n_h+1}^{m_k} (\theta_n - \theta_0(m_k \epsilon)) \right| < M_k (M_k \epsilon \kappa + \epsilon \tau).
\]
Thus, using only $M_k\epsilon < 2M^{-4}$ and $M^{-\frac{13}{2}} < \epsilon$, we get

\begin{equation}
(19) \quad \left| \exp \left( i \sum_{n=m_k+1}^{m_k} \theta_n \right) - \exp \left[ i(m_k - n_h)\mathcal{B}(m_k\epsilon) \right] \right| < M_k(M_k\epsilon \beta + \epsilon) < M_k \epsilon^2 + 2 \epsilon M^{-4}
\end{equation}

for $m_{k-1} \leq n_h < m_k$. Second, by the definition of $\beta$,

\begin{equation}
(20) \quad |r_{m_k}^k - r_{m_k}^k| < M_k\epsilon \beta + 2\epsilon < 2\beta M^{-1} + 2\gamma M^{-6}
\end{equation}

whenever $m_{k-1} \leq n_h < m_k$. Putting (19) and (20) together, we find that whenever $m_{k-1} \leq n_h < m_k$,

\begin{equation*}
\left| r_{m_k}^k \exp \left( i \sum_{n=m_k}^{m_k} \theta_j \right) - r_{m_k}^k \exp \left[ i(m_k - n_h)\mathcal{B}(m_k\epsilon) \right] \right| < \mathcal{C} M^{-\frac{3}{2}}
\end{equation*}

for some constant $\mathcal{C}$ depending only on the functions $q$ and $\phi$. Using the same two inequalities as for the bound (19) and the fact that there are $M_k$ elements in the sums $\Omega_k$ and $\Omega_k$, this estimate implies

\begin{equation}
(21) \quad |\Omega_k - \overline{\Omega}_k| < 2\mathcal{C} M.
\end{equation}

To bound the quantities $\overline{\Omega}_k$, we write

\begin{equation*}
\overline{\Omega}_k = r_{m_k}^k \sum_{n=1}^{M_k} \exp(i\mathcal{B}(m_k\epsilon)),
\end{equation*}

whence

\begin{equation}
(22) \quad |\overline{\Omega}_k| \leq \alpha \left| \frac{\exp(iM_k\mathcal{B}(m_k\epsilon)) - 1}{\exp(i\mathcal{B}(m_k\epsilon)) - 1} \right| < \frac{\alpha}{\sigma}
\end{equation}

where $\sigma$ is as defined above. Combining (21) and (22) with our assumption that $M > 2$ yields

\begin{equation}
(23) \quad |\Omega_k| < \mathcal{C} M.
\end{equation}

Going back to (18) and using that $\epsilon K < M^{-2}$, we get

\begin{equation*}
|\Omega| < CM^{-1}
\end{equation*}

where the constant $\mathcal{C}$ depends only on $q$ and $\phi$. Then going back to (17), we finally obtain the result

\begin{equation*}
|\mathcal{Y}| < \frac{\alpha^k}{(k-1)!} CM^{k-1} < \frac{\alpha^k}{(k-1)!} C\mathcal{C}.
\end{equation*}
The Lemma follows by taking
\[ \bar{\varrho} = \min \left\{ \frac{\varrho}{C}, \frac{1}{2} \cdot 2^{-\delta} |b - x_\ast|^{\delta} : x_\ast \text{ a turning point} \right\} \]
and \( \varepsilon' = \bar{\varrho}^6. \)

**Proposition 5.** Let \([a, b]\) be an oscillatory interval with positive distance from the set of turning points, and let \( \varrho > 0 \) be given. Then there exists \( \varepsilon' > 0 \) sufficiently small such that whenever \( 0 < \varepsilon < \varepsilon' \),

\[ T^n = \begin{bmatrix} e^{S_{\varepsilon'}(a, b)} + \bar{\varrho}^{11} & \bar{\varrho}^{12} \\ \bar{\varrho}^{21} & e^{S_{\varepsilon'}(b, a)} + \bar{\varrho}^{22} \end{bmatrix} \begin{bmatrix} \prod_{n=a}^{b} \lambda^{+}_n & 0 \\ 0 & \prod_{n=a}^{b} \lambda^{-}_n \end{bmatrix} \]

for some complex numbers \( \bar{\varrho}^j \) such that \( |\bar{\varrho}^j| < \varrho \) for \( i, j = 1, 2 \).

**Remark.** The convergence of the left-hand factor to a diagonal form as \( \varepsilon \) tends to zero is not uniform as \( a \) or \( b \) nears a turning point. However, it is uniform over all \( x \)-intervals whose distance from any turning point is bounded below by some positive number. Notice that \( S_{\varepsilon'}(a, b) \) depend on the choice of eigenvectors.

Part (1) of Theorem 2 can be deduced from Proposition 5, though the details are not presented here.

**Proof.** Consider first \( \varepsilon^L \) times the diagonal matrix in expression (15) for \( T_k \). The quantities \( \varepsilon^L \sum_{a \leq n_1 < \ldots < n_L \leq b} \lambda^{n_1} \cdots \lambda^{n_L} \) are essentially Riemann sums for the integrals
\[ \int \cdots \int_{\mathbb{R}^L} L^{n_1}(x_1) \cdots L^{n_L}(x_L) \, dx_1 \cdots dx_L \]
in which the integration is over the subregion \( \mathbb{R}^L \) of \([0, 1]^L\) described by the inequalities \( a < x_1 < \ldots < x_L < b \). These integrals are in fact equal to
\[ \frac{1}{L!} \int_a^b \cdots \int_a^b L^{n_1}(x_1) \cdots L^{n_L}(x_L) \, dx_1 \cdots dx_L = \frac{1}{L!} \left( \int_a^b L^{n_1}(x) \, dx \right)^L = \frac{1}{L!} (S_{\varepsilon'}(a, b))^L. \]
The sum over all \( L \) should then converge to \( e^{S_{\varepsilon'}(a, b)} \). This can be made rigorous, but the details are omitted.

Regarding the second summand of \( \varepsilon^L P_k \) in equation (15), we see that any one of its entries contains no more that \( 2^{L-1} \) terms of the type \( Y \), and so by Lemma 4, given \( \varrho > 0 \), the sum over all these terms can be made to be less in modulus than \( \bar{\varrho}^{(2\alpha)/(L-1)} \) for each \( L \) by taking \( \varepsilon \) sufficiently small, and thus, in the sum over all \( L \), this second summand is less than \( \bar{\varrho} \exp(2\alpha) \) in modulus to any entry of the matrix \( \sum_{L=1}^{\infty} \varepsilon^L P_k \). \( \square \)
5.3. Exponential region. We now turn to an exponential region $[a, b]$. Let us suppose, for the sake of the argument, that $0 < \lambda^{-}(x) < \lambda^{+}(x)$ on this interval. Referring to the form of $P_{\epsilon}$ computed on page 15, we observe that each entry of its second column consists of terms containing a factor of the form $\prod_{i=1}^{n} \frac{\lambda_{n}^{+}}{\lambda_{n}^{-}}$, which are summed over $n_{1} < ... < n_{\ell} \leq \pi$, and one expects these to converge to zero as $\epsilon \to 0$ since $\frac{\lambda_{n}^{+}}{\lambda_{n}^{-}} < 1$. The first column contains a sum over $n_{1} < ... < n_{\ell} \leq \pi$ of terms of the form $\prod_{i=n_{h}+1}^{n_{h}+1} \frac{\lambda_{n}^{+}}{\lambda_{n}^{-}}$, but $n_{h+1}$ is never equal to $\pi$ except in the term containing the product $\frac{\lambda_{n}^{+}}{\lambda_{n}^{-}} \cdots \frac{\lambda_{n_{\ell}}^{+}}{\lambda_{n_{\ell}}^{-}}$, which has $\prod_{i=n_{h}+1}^{n_{h}} \frac{\lambda_{n}^{+}}{\lambda_{n}^{-}}$ as a factor. This suggests that, although both entries of the first column diverge as $\epsilon \to 0$, the upper left entry will dominate. This can be proved rigorously as long as the interval $[a, b]$ is bounded away from any turning point. Suppose that, for some fixed value of $s$ with $0 < s < 1$,

$$\frac{\lambda^{-}(x)}{\lambda^{+}(x)} < s \quad \text{for} \quad x \in [a, b],$$

and let $\alpha, \beta, \gamma$, and $S_{1}(a, b)$, be defined as before ($\alpha$, $\beta$, and $\gamma$ depend on $s$). The following proposition makes precise what is meant by the dominance of the $(1, 1)$-entry of $T_{\epsilon}$.

**Proposition 6.** Let $[a, b] \text{ be an exponential interval with positive distance from the set of turning points, and assume that } 0 < \lambda^{-}(x) < \lambda^{+}(x) \text{ for every } x \text{ in } [a, b]. \text{ Then, for any } \varrho > 0, \, \epsilon' > 0 \text{ can be chosen sufficiently small such that}

$$T_{\epsilon'} = \left[ \begin{array}{cc} e^{S_{1}(a, b)} + \varrho_{11} & \varrho_{12} \\ \varrho_{21} & \varrho_{22} \end{array} \right] \prod_{n=1}^{\pi} \lambda_{n}^{+}$$

whenever $0 < \epsilon < \epsilon'$, for certain numbers $\varrho_{ij}$ with modulus less than $\varrho$.  

Proof is omitted.

**Remark.** The convergence of the left-hand matrix as $\epsilon$ tends to zero is not uniform as $a$ or $b$ nears a turning point since a suitable value of $s$ approaches 1 near a turning point. However, it is uniform over all exponential $x$-intervals whose distance from any turning point is bounded below by some positive number.

Part (2) of Theorem 2 follows from Proposition 6.
