The Kirchhoff Plate Equation on Surfaces:
The Surface Hellan–Herrmann–Johnson Method

SHAWN W. WALKER†

[Received on 13 August 2020]

We present a mixed finite element method for approximating a fourth order elliptic PDE, the Kirchhoff plate equation, on a surface embedded in \( \mathbb{R}^3 \), with or without boundary. Error estimates are given in mesh dependent norms that account for the surface approximation and the approximation of the surface partial differential equation. The method is built on the classic Hellan–Herrmann–Johnson (HHJ) method (for flat domains), and convergence is established for \( C^{k+1} \) surfaces, with degree \( k \) (Lagrangian, parametrically curved) approximation of the surface, for any \( k \geq 1 \). Mixed boundary conditions are allowed, including clamped, simply-supported, and free conditions; if free conditions are present, then the surface must be at least \( C^{2,1} \).

The framework uses tools from differential geometry and is directly related to the seminal work of Dziuk (1988) for approximating the Laplace-Beltrami equation. The analysis here is the first to handle the full surface Hessian operator directly. Numerical examples are given on non-trivial surfaces that demonstrate our convergence estimates. In addition, we show how the surface biharmonic equation can be solved with this method.

Keywords: surface Kirchhoff plate ; surface biharmonic ; surface finite elements ; open surfaces ; mesh-dependent norms ; geometric consistency error ; non-conforming method.

1. Introduction

Physical models involving partial differential equations on surfaces have become quite popular, e.g., surface tension driven droplet motion Barrett et al. (2015); Gerbeau & Lelièvre (2009); Walker et al. (2009), surface diffusion Bänsch et al. (2005); Smereka (2003), the Stefan problem Barrett et al. (2010); Davis & Walker (2015, 2017), elastic bending problems Timoshenko & Woinowsky-Krieger (1959); Barrett et al. (2007); Bartels et al. (2015, 2012), biomembranes Du et al. (2005, 2004); Zhong-can & Helfrich (1989); Dziuk (2008); Bonito et al. (2010); Barrett et al. (2016), and other diffusive processes on surfaces Elliott & Ranner (2015); Elliott & Stinner (2010); Elliott et al. (2012). In particular, fourth order elliptic operators appear in some of these applications, e.g., biomembranes Bonito et al. (2011); Elliott & Stinner (2010) and the surface Cahn-Hilliard equation Elliott & Ranner (2015). In this paper, we develop and analyze a finite element method (FEM) to solve the surface version of the Kirchhoff plate equation. In addition, we show how the method can be used to solve the surface bi-Laplace equation.

It is well-known that fourth order elliptic equations present difficulties for FEMs, even in the flat case. One issue is dealing with the Sobolev space \( H^2 \). Another is correctly capturing fourth order

type boundary conditions; in fact, the classic Babuška paradox illustrates this beautifully Babuška et al. (1980). Amongst the various methods for the Kirchhoff plate problem, the Hellan–Herrmann–Johnson (HHJ) mixed method is one of the most powerful Brezzi & Marini (1975); Brezzi & Raviart (1976); Brezzi et al. (1980); Babuška et al. (1980); Arnold, D. N. & Brezzi, F. (1985); Comodi (1989); Blum & Rannacher (1990); Stenberg, Rolf (1991); Krendl et al. (2016); Rafetseder & Zulehner (2018). It yields stable discretizations of any order and does not succumb to the Babuška paradox Arnold & Walker (2020). In this paper, we extend the HHJ method to surfaces, with or without boundary, and analyze the effect of the approximation of the surface using Lagrange (parametric) elements of any degree.

Numerical approximation of fourth order elliptic surface PDEs, especially the effect of approximating the geometry, is not as well established as for second order problems Deckelnick et al. (2005); Dziuk (1988); Dziuk & Elliott (2013). For instance, the geometric consistency error when solving the Laplace-Beltrami equation \(-\Delta_{\Gamma} u = f\) on a closed, smooth surface \(\Gamma\) has been analyzed in Dziuk (1988); Demlow & Dziuk (2007); Demlow (2009). The main argument of their analysis is to first approximate the domain \(\Gamma\) with a degree \(m\) (Lagrangian) approximation \(\Gamma^m\) with elements of size \(h\); the approximation can be generated using a signed distance function (i.e. closest point map) or interpolation of chart parameterizations. Next, in order to compare approximate solutions obtained on the approximation domain to the exact solution on the exact domain, we need a diffeomorphic mapping \(\Psi : \Gamma^m \to \Gamma\). Then, the geometric consistency error is estimated by measuring the change in the metric of the surface from \(\Gamma^m\) to \(\Gamma\) with this mapping. The geometric error reduces to showing the following estimate for the Jacobian of the map: \(\|\nabla (\Psi - \text{id}_{\Gamma^m})\|_{L^\infty(\Gamma^m)} = O(h^m)\). Hence, choosing \(m\) to equal or exceed the degree of the finite elements used to approximate the solution guarantees optimal approximation order.

The surface biharmonic problem has been solved using surface finite elements via splitting the PDE into two second order equations, such as in Dziuk & Elliott (2013); Elliott & Ranner (2015) for solving the surface Cahn-Hilliard equation. The geometric consistency error is estimated in a similar way as for the Laplace-Beltrami equation. Of particular relevance to our paper is Larsson & Larson (2017), in which the surface biharmonic problem is discretized more directly using a discontinuous Galerkin (dG) approach (without splitting the equation) and piecewise linear domain approximation of a closed surface. Their analysis also involves estimating the Jacobian, as well as accounting for the geometric error of surface dG operators for the Laplace-Beltrami operator, as well as jump and stabilization terms.

1.1 Main Contributions

The surface biharmonic problem. Aside from being the first method to solve the surface Kirchhoff plate problem, which was first (and possibly last) mentioned in Lasiecka et al. (2003), it can be used to solve the biharmonic problem on a surface. In the case of flat domains, any method for the Kirchhoff plate problem can be used to solve the biharmonic problem with clamped, or periodic, boundary conditions. The same applies to the surface problem, but the Gauss curvature of the surface now appears in the strong form PDE. In Section 7.4, we show a numerical example for the surface biharmonic problem and justify the approximation for small negative Gauss curvature.

Approximation of the surface Hessian. The classic HHJ method (for flat domains) involves the full Hessian of the displacement, in a non-conforming way, and the same is true in our formulation which utilizes the surface Hessian. Estimating the geometric consistency error when the Hessian is in the PDE is difficult because of the second derivatives of the diffeomorphism \(\Psi : \Gamma^m \to \Gamma\) that appear in the analysis (see (Boffi et al., 2013, pg. 78) and (Ciarlet, 2002, Thm. 4.4.3)). For example, let \(\Gamma\) and \(\Gamma^m\) be mapped to a common reference domain using \(\chi\) and \(\tilde{\chi}\), respectively, and note that the
Hessian of \( v: \Gamma \to \mathbb{R} \) maps as \( \nabla_\alpha \nabla_\beta v = \left[ \partial_\alpha \partial_\beta \bar{v} - \partial_\gamma \bar{v} \Gamma^\gamma_{\alpha\beta} \right] \), where \( \Gamma^\gamma_{\alpha\beta} \) are the Christoffel symbols of the second kind for the induced metric, and \( \bar{v} = v \circ \chi \). Since \( \Gamma^\gamma_{\alpha\beta} \) depend on second derivatives of the map, then comparing Christoffel symbols for \( \chi \) and \( \tilde{\chi} \) yields \( \| \Gamma^\gamma_{\alpha\beta} - \tilde{\Gamma}^\gamma_{\alpha\beta} \|_{L^\infty} = O(h^{m-1}) \). Ergo, an improper handling of this term would yield sub-optimal results or no convergence at all for \( m = 1 \).

Another related issue is handling the jump terms (in the mesh dependent 2-norm) when affected by the nonlinear map. A crucial tool that overcomes these issues, and is special to the HHJ formulation, is a Fortin-like operator (5.8). Moreover, we do not require the diffeomorphism to be the closest point map coming from a signed distance function; interpolants of local charts can be used. Of course, one can still use the closest point map.

SURFACES WITH OR WITHOUT BOUNDARY. Our analysis assumes the surface is described by charts that exactly capture the boundary (if there is one). The approximate surface is built by interpolating these maps. For smooth, closed, embedded surfaces, one can use the closest point map built from a signed distance function to create the approximate surfaces Dziuk (1988); Demlow & Dziuk (2007); Demlow (2009); this method is very convenient for the analysis. However, it is not so convenient for approximating a surface with boundary. In addition, the order of differentiability of the closest point map is one less than that of the surface, which is a technical annoyance avoided by the use of charts.

Moreover, our analysis allows for a variety of boundary conditions, such as clamped, simply-supported, and free. Using the result from Walker (2020), we establish convergence of the surface HHJ scheme even if uniform free boundary conditions are used and the discrete surface is piecewise linear. This is not trivial because of the presence of Killing fields (see Remark 2.1). Our mixed formulation can also handle “point conditions” (see Section 2.2 and (2.3)).

GENERAL ERROR ESTIMATES. We make minimal regularity assumptions, in-line with the known regularity for the plate problem with various mixed boundary conditions. Furthermore, if the surface and solution are smooth, we obtain optimal convergence of order \( r + 1 \), where \( r + 1 \) is the degree of the Lagrange space used, both for the surface approximation and the displacement variable.

1.2 Outline

Section 2 presents the Kirchhoff plate problem on a surface and Section 3 presents the mesh-dependent, mixed formulation that is the surface version of the classic HHJ method. In Section 4, we review parametric surface elements, describe the surface Matrix Piola transform, which is needed for mapping HHJ elements, and derive some change of variable results when mapping the bilinear forms. Section 5 presents the finite element method for the mesh-dependent, mixed formulation, and verifies the well-posedness of the method. Section 6 gives the error analysis. The PDE error is analyzed as in Babuška et al. (1980) and Blum & Rannacher (1990) (for the case of a flat domain), where we use mesh dependent spaces and norms; the geometric error is analyzed in the framework of Dziuk (1988); Dziuk & Elliott (2013) combined with new results we derive here. Section 7 presents numerical results and we conclude in Section 8 with some comments. In the appendix, we give an overview of essential differential geometry concepts and provide some technical results.
2. The Plate Equation on a Surface

Let $\Gamma$ be a smooth, connected, 2-dimensional manifold embedded in $\mathbb{R}^3$ with continuous, piecewise smooth boundary $\partial \Gamma =: \Sigma = \Sigma_c \cup \Sigma_s \cup \Sigma_f$ that consists of clamped ($\Sigma_c$), simply-supported ($\Sigma_s$), and free sections ($\Sigma_f$); see Figure 1. In some cases, the boundary may be empty, giving a closed manifold.

2.1 Sobolev Spaces on Surfaces

We adopt standard notation for Sobolev spaces on manifolds. For example, the $H^1(\Gamma)$ and $H^2(\Gamma)$ inner products on $\Gamma$ are written:

$$
(w, v)_{H^1(\Gamma)} := \int_{\Gamma} w v + \nabla_{\Gamma} w \cdot \nabla_{\Gamma} v dS,
(w, v)_{H^2(\Gamma)} := (w, v)_{H^1(\Gamma)} + \int_{\Gamma} \nabla \nabla_{\Gamma} w : \nabla \nabla_{\Gamma} v dS,
$$

where $\nabla_{\Gamma} v \equiv \text{grad}_{\Gamma} v$ is the surface gradient of $v$ in (A.8) and $\nabla \nabla_{\Gamma} w \equiv \text{hess}_{\Gamma} w$ is the surface Hessian of $v$ in (A.9). See Section A.2 for details of the notation and definitions of the differential operators.

We denote by $\mathring{H}^\ell(\Gamma) \subset H^\ell(\Gamma)$ the Sobolev space with vanishing boundary conditions up to degree $\ell - 1$. We will have special use of the following subspace of $H^2(\Gamma)$: $\mathcal{Y}(\Gamma) := \{ w \in H^2(\Gamma) \mid w = 0, \ n \cdot \nabla_{\Gamma} w = 0, \ on \ \Sigma_c \cup \Sigma_s \}$, i.e. with clamped and simply-supported boundary conditions.

Next, let $\mathcal{Z}(\Gamma) := \{ w \in \mathcal{Y}(\Gamma) \mid \nabla \nabla_{\Gamma} w = 0 \}$ be the nullspace of the (covariant) surface Hessian operator on $\Gamma$. The maximum dimension of $\mathcal{Z}(\Gamma)$ is three for a two dimensional surface; see (Walker, 2020, Sec. 2.2.2). Furthermore, if $v \in \mathcal{Z}(\Gamma)$ is not constant, then $\nabla_{\Gamma} v$ is a Killing field (do Carmo (1992), (Eisenhart, 1926, eqn. (70.2)), (Petersen, 2006, Prop. 27).

REMARK 2.1 Generic manifolds, with non-constant Gauss curvature, do not have Killing fields. Ergo, even if $\partial \Gamma = \Sigma_f$, $\mathcal{Z}(\Gamma)$ may only contain constants. On the other hand, consider the closed 2-sphere. It has 3 Killing fields corresponding to 3 independent rotations of the sphere, but none of them come from differentiating a scalar $w$ (so $\mathcal{Z}(\Gamma)$ only contains constants).

Next, consider a small spherical cap with boundary (and free boundary conditions). Two of the Killing fields can be written as a gradient, but the third one is a rotation about a point in the surface so does not correspond to the gradient of a scalar (see (do Carmo, 1992, Ch. 4, exer. 3.)). In this case, $\mathcal{Z}(\Gamma)$ is spanned by three basis functions, i.e. two non-constant functions whose gradients are killing fields and the unit constant function. See Section 7.2 for a numerical example.
2.2 The Bending Energy on a Surface

Owing to the continuous embedding $H^2(\Gamma) \hookrightarrow C^0(\mathcal{T})$, point evaluation is well-defined. Therefore, set $J = \dim \mathcal{Z}(\Gamma)$ and choose points $\{p_j\}_{j=1}^J \subset \Gamma$ such that $\{v \in \mathcal{Z}(\Gamma) \mid v(p_j) = 0, 1 \leq j \leq J\} \equiv \{0\}$; see (Walker, 2020, Sec. 2.2.2) for how this can be done. Note that if $J \equiv 0$, then $\{p_j\}_{j=1}^J \equiv \emptyset$. Moreover, define $\mathcal{E}(f) := \left(\sum_{j=1}^J |f(p_j)|^2\right)^{1/2}$ for all $f \in H^2(\Gamma)$ if $J > 0$; otherwise, $\mathcal{E}(f) \equiv 0$. Then, the “plate energy” on the surface is given by

$$\mathcal{E}[w] = \frac{1}{2} \langle \mathbf{C} \nabla \nabla_{\Gamma} w, \nabla \nabla_{\Gamma} w \rangle_\Gamma - \langle f, w \rangle_\Gamma,$$ for all $w \in \mathcal{W}$, where

$$\mathcal{W}(\Gamma) = \{w \in \mathcal{W}(\Gamma) \mid \mathcal{E}(w) = 0\},$$

is the space of “displacements,” $f \in \mathcal{W}^*$, and $\langle f, w \rangle_\Gamma$ is the duality pairing between $\mathcal{W}^*$ and $\mathcal{W}$, and $\mathbf{C}$ is the constitutive 4-tensor:

$$\mathbf{C} \mathbf{t} := D[(1-\zeta)\mathbf{t} + \zeta \mathbf{t} \cdot \mathbf{I}], \quad \mathbf{K} \mathbf{t} := \frac{1}{D} \left[\frac{1}{1-\zeta} \mathbf{t} - \frac{\zeta}{1-\zeta^2} \mathbf{t} \cdot \mathbf{I}\right],$$

defined for all symmetric tensors $\mathbf{t} \in \mathbb{R}^{3 \times 3}$, with $\mathbf{K}$ the inverse of $\mathbf{C}$. Note that $\mathbf{C}$ is a symmetric positive-definite operator on the space $\mathbb{S}(\Gamma)$ of symmetric, tangential $3 \times 3$ tensors, provided $\zeta \in (-1, 1)$; for general symmetric $3 \times 3$ tensors, $\mathbf{C}$ is positive definite if $\zeta \in (-1/2, 1)$.

The Kirchhoff plate model on a surface follows by minimizing the energy (2.2), which gives the weak formulation as follows: find $w \in \mathcal{W}$ such that

$$\int_{\Gamma} \mathbf{\sigma} : \nabla \nabla_{\Gamma} z dS = \langle f, z \rangle_\Gamma,$$ for all $z \in \mathcal{W},$$

where $\mathbf{\sigma} = \mathbf{C} \nabla \nabla_{\Gamma} w$. The solvability of (2.5) is guaranteed because (2.2) is a convex functional with a unique minimizer. Moreover, $(\mathbf{C} \nabla \nabla_{\Gamma} w, \nabla \nabla_{\Gamma} w)_\Gamma \geq C_0 \|
abla \nabla_{\Gamma} w\|_{L^2(\Gamma)}^2 \geq C_1 \|w\|_{H^2(\Gamma)}^2$, by Poincaré (c.f. (4.7)), so the unique solution of (2.5) follows by the Lax-Milgram lemma (Evans 1998) with a priori estimate $\|w\|_{H^2(\Gamma)} \leq C \|f\|_{\mathcal{W}^*}$. The strong form PDE is $\mathbf{\sigma} = \mathbf{C} \nabla \nabla_{\Gamma} w$, and

$$\text{div} \nabla_{\Gamma} \mathbf{\sigma} = f, \quad \text{in } \Gamma \setminus \{p_j\}_{j=1}^J, \quad \text{and } w = 0, \quad \text{on } \Sigma_c \cup \Sigma_b,$$

$$\mathbf{n} \cdot \nabla_{\Gamma} w = 0, \quad \text{on } \Sigma_c, \quad \mathbf{n}^\text{cm} = 0, \quad \text{on } \Sigma_i \cup \Sigma_b,$$

$$\mathbf{n} \cdot (\nabla_{\Gamma} \mathbf{\sigma}) - \mathbf{t} \cdot \nabla_{\Gamma} \mathbf{\sigma}^\text{ct} = 0, \quad \text{on } \Sigma_t, \quad \mathcal{E}(w) = 0,$$

where $\mathbf{\sigma}^\text{ct} := \mathbf{n}^\text{ct} \mathbf{n} \mathbf{\sigma}^\text{ct} := \mathbf{n}^\text{ct} \mathbf{t} \mathbf{\sigma}$ denotes the conormal-conormal (conormal-tangent) component of $\mathbf{\sigma}$, and we have the additional corner conditions

$$-\left[\mathbf{n}^\text{ct} \mathbf{t}\right]_p = -\mathbf{\sigma}^\text{ct} \big|_{p}^{+} = 0, \quad \text{at every corner } p \text{ in } \Sigma_t.$$

3. Mixed Formulation of the Manifold Plate Problem

After stating the assumptions on the embedded surface domain $\Gamma$, we derive the continuous, mesh dependent formulation of the manifold plate problem in the extrinsic setting.
3.1 Domain Assumptions

The surface $\Gamma$ is taken to be $C^{k+1}$, where $k \geq 1$. If $\Gamma$ has a boundary $\partial \Gamma := \Sigma$, we assume $\Sigma$ is piecewise $C^{k+1}$ with a finite number of corners, with interior angle $\alpha_i \in (0, 2\pi]$ of the $i$th corner measured with respect to the Euclidean metric in $\mathbb{R}^3$ (see Figure 1). In particular, $\Sigma$ is globally continuous and parameterized by a piecewise curve, i.e., $\Sigma = \bigcup_{p \in \mathcal{V}_\Sigma} p \cup \bigcup_{\xi \in \mathcal{E}_\Sigma} \xi$, where $\mathcal{V}_\Sigma$ is the set of corner vertices and $\mathcal{E}_\Sigma$ is the set of (open) $C^{k+1}$ curves that make up $\Sigma$. Furthermore, as a technical convenience, we assume that $\Gamma$ is a sub-manifold of $\Gamma^*$ with $\overline{\Gamma} \subset \subset \Gamma^*$.

In addition, we assume $\Sigma = \Sigma_c \cup \Sigma_i \cup \Sigma_f$ partitions into three mutually disjoint one dimensional components $\Sigma_c$ (clamped), $\Sigma_i$ (simply supported), and $\Sigma_f$ (free). Any of the components can be empty, but if $|\Sigma_i| > 0$, then we also assume that $\Sigma$ is at least $C^{2,1}$. Each open curve $\xi \in \mathcal{E}_\Sigma$ belongs to only one of the sets $\Sigma_c$, $\Sigma_i$, or $\Sigma_f$ and each curve is maximal such that two distinct curves contained in the same component do not meet at an angle of $\pi$. Furthermore, we have the set of corner vertices contained in $\Sigma_i$:

$$\mathcal{V}_\Sigma = \{ p \in \mathcal{V}_\Sigma \mid p = \overline{\xi_{p^-}} \cap \overline{\xi_{p^+}}, \text{ where } \xi_{p^-}, \xi_{p^+} \subset \Sigma_i, \xi_{p^-} \neq \xi_{p^+} \}. \quad (3.1)$$

3.2 Continuous Mesh-dependent Formulation

The main difficulty in solving (2.5) numerically is that $W \subset H^{2}(\Gamma)$ and so $C^1$ elements are required for a conforming discretization. This is especially difficult in the case of a surface, e.g. one would need a surface version of the Argyris element Brenner & Scott (2008). Thus, we adopt the approach in Brezzi & Raviart (1976); Babuška et al. (1980); Arnold, D. N. & Brezzi, F. (1985); Blum & Rannacher (1990); Arnold & Walker (2020) and use a mesh-dependent version of $H^2(\Gamma)$. We partition $\Gamma$ with a mesh $\mathcal{T}_h = \{ T \}$ of triangles such that $\Gamma = \bigcup_{T \in \mathcal{T}_h} T$, where $h_T := \text{diam}(T)$ and $h := \max_T h_T$, and assume throughout that the mesh is quasi-uniform and shape regular. We also assume the corners of the domain are captured by vertices of the mesh. Note that these triangles are, in general, curved (recall Figure 1).

Next, we have the skeleton of the mesh, i.e. the set of mesh edges $\mathcal{E}_h := \partial \mathcal{T}_h$, which may be curved. Let $\mathcal{E}_{\partial,h} \subset \mathcal{E}_h$ denote the subset of edges that are contained in the boundary $\Sigma$ and respect the boundary condition partition of $\Sigma$. The internal edges are given by $\mathcal{E}_{0,h} := \mathcal{E}_h \setminus \mathcal{E}_{\partial,h}$.

The spaces in the following sections are infinite dimensional, but “mesh dependent.” Thus, we use standard dG notation for writing inner products and norms over the triangulation, e.g. $(f, g)_{\mathcal{T}_h} := \int_{T \in \mathcal{T}_h} f \cdot g \, dT$, $\| f \|^2_{L^2(\mathcal{T}_h)} := \sum_{T \in \mathcal{T}_h} \| f \|^2_{L^2(T)}$, etc. The following scaling/trace estimate is used judiciously (Agmon, 1965, Thm 3.10):

$$\| v \|^2_{L^2(\partial T)} \leq C \left( h^{-1} \| v \|^2_{L^2(T)} + h \| \nabla v \|^2_{L^2(T)} \right), \forall v \in H^1(T), T \in \mathcal{T}_h. \quad (3.2)$$

3.2.1 Skeleton Spaces. We follow Babuška et al. (1980) in defining infinite dimensional, but mesh dependent spaces and norms. A mesh-dependent version of $H^2(\Gamma)$ is given by

$$H^2_h(\Gamma) := \{ v \in H^1(\Gamma) \mid v|_T \in H^2(T), \text{ for } T \in \mathcal{T}_h \}, \quad (3.3)$$

with the following semi-norm

$$\| v \|^2_{\mathcal{E}_h} := \| \nabla v \|^2_{L^2(\mathcal{T}_h)} + h^{-1} \| \nabla v \|^2_{L^2(\mathcal{E}_{\partial,h})} + h^{-1} \| [n \cdot \nabla v] \|^2_{L^2(\Sigma)} \quad (3.4)$$

where $[\eta]$ is the jump in quantity $\eta$ across mesh edge $E$, and $n$ is the unit co-normal on $E \in \mathcal{E}_h$. Hence, if the edge $E$ is shared by two triangles $T_1$ and $T_2$ with outward co-normals $n_1$ and $n_2$, then
\[ \mathbf{n} \cdot \nabla_{\Gamma} \mathbf{v} = \mathbf{n}_1 \cdot \nabla_{\Gamma} \mathbf{v}|_{\Gamma_1} + \mathbf{n}_2 \cdot \nabla_{\Gamma} \mathbf{v}|_{\Gamma_2} \] on \( \Gamma \). For \( E \) a boundary edge, we set \( \| \mathbf{n} \| = \mathbf{n} \| E \| \). Next, let \( S = S(\Gamma) \) be the set of (extrinsic) tangential tensors on \( \Gamma \), i.e., \( S(\Gamma) := \{ \mathbf{\varphi} \in \mathbb{R}^{3 \times 3} \mid \mathbf{\varphi} = \mathbf{\varphi}^T, \mathbf{\varphi} \mathbf{v} \equiv 0 \} \), where \( \mathbf{v} \) is the unit normal vector of \( \Gamma \) (see (A.7)). For any \( \mathbf{\varphi} \in H^1(\Gamma; S) \) define
\[ \| \mathbf{\varphi} \|_{0,h} := \| \mathbf{\varphi} \|_{L^2(\Gamma)} + h \| \mathbf{n}^T \mathbf{\varphi} \mathbf{n} \|_{L^2(\Sigma_h)} + h \| \mathbf{n}^T \mathbf{\varphi} \mathbf{n} \|_{L^2(\Sigma_h)}, \] (3.5)
and define \( H^0_h \) to be the completion: \( H^0_h(\Gamma; S) := H^1(\Gamma; S) \|_{0,h} \). Note that \( H^0_h(\Gamma; S) \equiv L^2(\Gamma; S) \| H^1(\Gamma; S) \), i.e., \( \mathbf{\varphi} \in H^0_h(\Gamma; S) \) is actually \( \mathbf{\varphi} \equiv (\mathbf{\varphi}^T, \mathbf{\varphi}^m) \), where \( \mathbf{\varphi}^T \in L^2(\Gamma; S) \) and \( \mathbf{\varphi}^m \in L^2(\Sigma_h) \), with no connection between \( \mathbf{\varphi}^T \) and \( \mathbf{\varphi}^m \). We also have that \( \mathbf{\varphi} \in H^1(\Gamma; S) \subset H^0_h(\Gamma; S) \) implies \( \mathbf{n}^T \mathbf{\varphi}^m \mathbf{n} \|_{\Sigma_h} = \mathbf{\varphi}^m \) Babuška et al. (1980). Furthermore, we have a scalar valued function version of \( \| \cdot \|_{0,h} \):
\[ \| v \|_{0,h} := \| v \|_{L^2(\Gamma)} + h \| v \|_{L^2(\Sigma_h)}, \] (3.6)
which satisfies the estimate: \( \| v \|_{0,h}^2 \leq C \left( \| v \|_{L^2(\Gamma)}^2 + h^2 \| \nabla_{\Gamma} v \|_{L^2(\Gamma)}^2 \right) \), for some independent constant \( C \).

Next, introduce the following skeleton subspaces
\[ \mathcal{H}_h := \{ w \in H^2_0(\Gamma) \mid w = 0 \text{ on } \Sigma_\Sigma \cup \Sigma_s, \mathcal{Z}(w) = 0 \} \subset H^1(\Gamma), \]
\[ \mathcal{Y}_h := \{ \mathbf{\varphi} \in H^0_0(\Gamma; S) \mid \mathbf{\varphi}^m = 0 \text{ on } \Sigma_s \}, \] (3.7)
where \( \mathcal{H}_h \) is a mesh-dependent version of (2.3) and \( \mathcal{Y}_h \) is used for the stress \( \mathbf{\sigma} \); note that the point condition \( \mathcal{Z}(w) = 0 \) makes sense because of the continuous embedding \( H^2_0(\Gamma) \rightarrow C^0(\overline{\Gamma}) \) (see (4.6)). Note that (3.7) imposes essential and natural boundary conditions differently than in (2.3).

3.2.2 Mixed Skeleton Formulation. The mixed method for the plate equation on an extrinsic manifold is a surface version of the classic HHJ method. Its derivations is essentially the same as for flat domains (Arnold & Walker, 2020, Sec. 2), which we briefly summarize. Start by multiplying the first equation in (2.6) by a test function \( v \in \mathcal{H}_h \), integrate over a triangle \( T \), apply integration by parts (twice), and sum over all triangles. This yields the weak form \( b_h(\mathbf{\sigma}, v) = -\langle f, v \rangle_T \) for all \( v \in \mathcal{H}_h \), where
\[ b_h(\mathbf{\varphi}, v) := -\sum_{T \in \Sigma_h} \langle \mathbf{\varphi}, \text{hess}_{\Gamma} v \rangle_T + \sum_{E \in \Sigma_h} \langle \mathbf{\varphi}^m, [\mathbf{n} \cdot \nabla_{\Gamma} v] \rangle_E, \] (3.8)
for all \( \mathbf{\varphi} \in H^0_0(\Gamma; S) \) and \( v \in H^2_0(\Gamma) \). Furthermore, define
\[ a(\mathbf{\tau}, \mathbf{\varphi}) := (\mathbf{K} \mathbf{\tau}, \mathbf{\varphi})_T, \] (3.9)
for all \( \mathbf{\tau}, \mathbf{\varphi} \in H^0_0(\Gamma; S) \). Using that \( \mathbf{\sigma} = \mathbf{C} \nabla \mathbf{\varphi} \), and the continuity of \( \mathbf{n} \cdot \nabla_{\Gamma} w \), we have \( a(\mathbf{\sigma}, \mathbf{\varphi}) + b_h(\mathbf{\varphi}, w) = 0 \) for all \( \mathbf{\varphi} \in \mathcal{Y}_h \). Thus, the solution \( (\mathbf{\sigma}, w) \) of (2.5) satisfies the pair of equations:
\[ a(\mathbf{\sigma}, \mathbf{\varphi}) + b_h(\mathbf{\varphi}, w) = 0, \quad \forall \mathbf{\varphi} \in \mathcal{Y}_h, \]
\[ b_h(\mathbf{\sigma}, v) = -\langle f, v \rangle, \quad \forall v \in \mathcal{H}_h. \] (3.10)
Note that (3.10) still holds for \( f \in H^{-1}(\Gamma) \), where \( \langle \cdot, \cdot \rangle \) is the duality pairing between \( H^{-1} \) and \( \hat{H}^1 \). In the case of polygonal domains in \( \mathbb{R}^2 \), this method has been analyzed by numerous authors with different techniques. The mesh dependent analysis we give is based on techniques in Babuška et al. (1980); Blum & Rannacher (1990), which were generalized to piecewise curved domains in Arnold & Walker (2020). The equivalence of (3.10) for flat domains is described in Babuška et al. (1980), (Blum & Rannacher, 1990, Sec. 3), and Arnold & Walker (2020); the equivalence in the case of surfaces is similar.
4. Domain Approximation and Mappings

Given an embedded manifold $\Gamma$, with or without boundary, we assume we have access to an atlas of charts $\{(U_i, \chi_i)\}$ that parameterizes $\Gamma$, and that a piecewise linear triangulation that interpolates $\Gamma$ at the vertices can be generated provided the mesh size is sufficiently small. We refer to Demlow & Dziuk (2007); Demlow (2009); Dziuk & Elliott (2013); Dziuk (1988) for more discussion on these basic issues. The following sections review the basic theory of curved elements, describe how tangential tensors transform under a diffeomorphism, followed by a transformation rule for the forms in (3.8), (3.9).

4.1 Curved Triangulations

We review the parametric approach to approximating a manifold with a curvilinear triangulation $\mathcal{T}_h^m$ of order $m \geq 1$. We start with a conforming, shape-regular, piecewise linear triangulation $\mathcal{T}_h^1$ of a polyhedral domain $\Gamma^1$ that interpolates $\Gamma$ at the vertices; furthermore, the boundary vertices of $\Gamma^1$ (namely $\Sigma^1$) lie on the boundary of $\Gamma$. Let $\mathcal{P}_h$ be the set of triangles with one side on $\Sigma^1$ and, for convenience, assume the triangulation satisfies the following property.

Property 1 Each triangle in $\mathcal{T}_h^1$ has at most two vertices on the boundary and so has at most one edge contained in $\Sigma^1$.

We assume $\mathcal{T}_h^1$ is homeomorphic to an exact triangulation $\mathcal{T}_h$ of $\Gamma$ in the following sense. For each $T^1 \in \mathcal{T}_h^1$, there is a chart $(U, \chi)$, and a straight-edged triangle $T' \subset U$, such that the following holds.

(i) $T^1 = (\pi^1 \chi)(T')$, where $\pi^1$ is the standard continuous, nodal Lagrange interpolation operator with the usual approximation properties.

(ii) There is a unique $T \in \mathcal{T}_h$ such that $T = \chi(T')$.

With the above considerations, one can generate another atlas of charts $\{(\hat{T}, \chi_T)\}_{T \in \mathcal{T}_h}$, where for each $T \in \mathcal{T}_h$, $T = \chi_T(\hat{T})$, where $\hat{T}$ is the standard reference triangle. Thus, we can define a family of curved triangulations, $\mathcal{T}_h^m$, for $m \geq 1$ (all homeomorphic to $\mathcal{T}_h$) by

$$\mathcal{T}_h^m = \{ T^m \mid T^m = (\hat{T}^m \chi_T)(\hat{T}) \},$$

where $\hat{T}^m : C^0(\hat{T}) \to \mathcal{P}_m(\hat{T})$ is any degree $m$ Lagrange interpolation operator on $\hat{T}$ that yields a globally continuous interpolant $\mathcal{P}_h^m : C^0(\Gamma^1) \to C^0(\Gamma^1)$ in the following sense. For any $f \in C^0(\Gamma^1)$, define $\mathcal{P}_h^m$ element-wise by $\mathcal{P}_h^m f|_{T^1} := \left[ \hat{T}^m (f|_{T^1} \circ (\hat{T}^1 \chi_T)) \right] \circ (\hat{T}^1 \chi_T)^{-1}$. Thus, $\mathcal{P}_h^m$ has the usual approximation properties Brenner & Scott (2008); Lenoir (1986). Later, we use a specific choice for $\mathcal{P}_h^m$ given by (5.2).

Therefore, $\mathcal{T}_h^m$ is a conforming, shape regular triangulation that approximates $\Gamma$ by $\Gamma^m := \bigcup_{T^1 \in \mathcal{T}_h^1} T^m$, for all $m \geq 1$. We also denote by $E_{0,h}^m$ the set of edges of the triangulation $\mathcal{T}_h^m$, which is partitioned into interior edges $E_{0,h}^m$ and boundary edges $E_{\partial,h}^m$. Thus $\Sigma^m := \bigcup_{E^m \in E_{\partial,h}^m} E^m$ is an $m$th order approximation of $\Sigma$.

Next, for each $T^1 \in \mathcal{T}_h^1$, we define the mapping $F : \Gamma^1 \to \Gamma$ through the diffeomorphism $F_T \equiv F|_{T^1} := \chi_T \circ (\mathcal{P}_h^1 \chi_T)^{-1}$, as well as the map $F^m : \Gamma^1 \to \Gamma^m$ by $F^m := \mathcal{P}_h^m F$, i.e. the map is defined by specifying the images of the Lagrange nodes of degree $m$ on $T^1$. Note that $F_T^1 \equiv \text{id}_{T^1}$. Moreover, we
define maps (see Figure 2) between approximate domains, of degrees \( l \) and \( m \) by

\[
\Phi_{lm}^{m}|_{T} = \Phi_{lm}^{m} : T^{l} \to T^{m}, \text{ where } \Phi_{lm}^{m} := \Phi_{lm}^{m} \circ (F_{T}^{m})^{-1}, \text{ so } \Phi_{lm}^{m} \equiv \Phi_{lm}^{m}.
\]

(4.2)

We also require a map from the approximate domain \( \Gamma^{m} \) to the exact domain \( \Gamma \). Specifically, given a triangle \( T^{m} \in T_{h}^{m} \), we define a diffeomorphism \( \Psi_{T}^{m} : T^{m} \to T \in T_{h} \) by \( \Psi_{T}^{m} := F_{T} \circ (F_{T}^{m})^{-1} \), so then \( T_{h}^{m} \equiv T_{h} \). The \( \Psi_{T}^{m} \) may be pieced together to give a global map \( \Psi_{T}^{m} : \Gamma^{m} \to \Gamma \).

The exact domain, and its corresponding triangulation, can be viewed as the limiting case of the approximate domain, and its triangulation, as \( m \to \infty \). Ergo, we adopt the following notations \( \Gamma^{\infty} \equiv \Gamma \), \( T^{m}_{h} \equiv T_{h}, \Phi^{m}_{l} \equiv \Phi^{l}, F_{T}^{m} \equiv F_{T}^{l} \), etc., which will sometimes be convenient. However, this is merely a choice of notation. We make no claim on the convergence of the polynomial approximate domains to the true domain as \( m \to \infty \).

The main approximation properties for these maps are summarized in the next theorem.

**THEOREM 4.1** For all \( 1 \leq l \leq m \leq k \) and \( m = \infty \), the maps \( F_{T}^{m}, F_{T}^{l} \) described above satisfy

\[
\|\nabla_{T}^{s} (F_{T}^{l} - \text{id}_{T})\|_{L^{\infty}(T)} \leq Ch^{2-s}, \text{ for } s = 0, 1, 2,
\]

\[
\|\nabla_{T}^{s} (F_{T}^{m} - F_{T}^{l})\|_{L^{\infty}(T)} \leq Ch^{l+1-s}, \text{ for } 0 \leq s \leq l + 1,
\]

(4.3)

\[
1 - Ch \leq \|\nabla_{T} (F_{T}^{l})^{-1}\|_{L^{\infty}(T)} \leq 1 + Ch, \quad \|\nabla_{T} (F_{T}^{l})^{-1} - I\|_{L^{\infty}(T)} \leq Ch,
\]

where all constants depend on the \( C_{k+1} \) norm of \( \Gamma \).
Next, recall the tangent $t$, co-normal $n$, and surface normal vectors $\nu$ from Figure 1 and let $\tilde{\nu}$, $\hat{\nu}$, or $\tilde{\nu}$ denote quantities defined on $T'$, or using $F^l_T$, for $s = m, l$, or $1$, respectively; e.g. $\hat{\nu}$ is the surface normal of $T^m$ (see Figure 3). Then, the following estimate holds:

$$
||\tilde{t} \circ F^m_T - \hat{t} \circ F^l_T||_{L^2(T^1)} + ||\tilde{n} \circ F^m_T - \hat{n} \circ F^l_T||_{L^2(T^1)} + ||\tilde{\nu} \circ F^m_T - \hat{\nu} \circ F^l_T||_{L^2(T^1)} \leq Ch^l. 
$$

(4.4)

![Fig. 3. Mapping unit vectors on $T^m$ back to $T^1$. We sometimes abuse notation and write $\nu \equiv \nu \circ F^m_T$, etc.](image)

We close with some results on how the mesh-dependent norms $\| \cdot \|_{0,h}$ and $\| \cdot \|_{2,h}$ transform between different domain approximations $\Gamma^m$ and $\Gamma^l$. Thus, let $\| \cdot \|_{2,h,m}$, $\| \cdot \|_{0,h,m}$ denote the norms in (3.4), (3.6) but defined on $\Gamma^m$. The proof of Proposition 4.2 is a straightforward application of basic mapping arguments and estimating Jacobians.

**PROPOSITION 4.2** Let $v \in H^2_h(\Gamma^m)$ and define $\hat{\nu} = v \circ \Phi \in H^2_h(\Gamma^l)$, $\Phi|_T := \Phi|_{T^m}$ for any choice of $l, m \in \{1, 2, ..., k, \infty\}$. Then,

$$
\|\nabla \Gamma^m v\|_{L^2(\partial \Gamma^m)} \leq C \left( \|\nabla \Gamma^l \hat{\nu}\|_{L^2(\partial \Gamma^l)} + h^{\min(l,m)} \|\nabla \Gamma^m \hat{\nu}\|_{L^2(\Gamma^l)} \right),
$$

$$
\|v\|_{2,h,m} \leq C \left( \|\hat{\nu}\|_{2,h,l} + h^{\min(l,m)} \|\nabla \Gamma^l \hat{\nu}\|_{L^2(\Gamma^l)} \right),
$$

for some constant $C > 0$ depending only on the domain.

**PROPOSITION 4.3** Let $1 \leq m \leq k$ and $m = \infty$. For all $v \in H^2_h(\Gamma^m)$, there holds

$$
\|v\|_{L^2(\Gamma^m)} \leq C_{int} \left( \|v\|_{H^1(\Gamma^m)}^2 + \|\nabla \Gamma^m v\|_{L^2(\Gamma^m)}^2 \right)^{1/2},
$$

$$
\|\nabla \Gamma^m v\|_{L^2(\Gamma^m)} \leq C_{tr} \left( \|\nabla \Gamma^m v\|_{L^2(\Gamma^m)}^2 + \|\nabla \Gamma^m v\|_{L^2(\Gamma^m)}^2 \right)^{1/2},
$$

for constants $C_{int}, C_{tr} > 0$ independent of $h$. Moreover, $\| \cdot \|_{2,h,m}$ is a norm on $\mathcal{H}^m_h$, and for $h > 0$ sufficiently small (depending only on $\Gamma$), there is a constant $C_P > 0$, depending only on $\Gamma$ and independent of $h$, such that

$$
\|v\|_{L^2(\Gamma^m)} + \|\nabla \Gamma^m v\|_{L^2(\Gamma^m)} \leq C_P \|v\|_{2,h,m}, \text{ for all } v \in \mathcal{H}_h^m.
$$

(4.7)

**Proof.** When $m = 1$, the proof is given in (Walker, 2020, Thm. 4.2). For $m > 1$, the $m = 1$ case is combined with (4.5). \( \square \)

**PROPOSITION 4.4** Assume the hypothesis of Proposition 4.2, and let $u \in H^1(\Gamma^m)$ and define $\hat{u} = u \circ \Phi \in H^1(\Gamma^l)$. Then, for $h > 0$ sufficiently small,

$$
C_0^{-1} \|\hat{u}\|_{0,h,l} \leq \|u\|_{0,h,m} \leq C_0 \|\hat{u}\|_{0,h,l}, \text{ and}
$$

(4.8)

where \( C_0, C_2 > 0 \) depend only on \( \Gamma \).

**Proof.** Inequality (4.8) follows by standard mapping arguments, and (4.9) follows by combining (4.5) and (4.7).

4.2 The Piola Transform

Recall the space of tangential, tensor-valued functions \( H^4_{\Gamma}(\Gamma^m; S^m) \) (see Section 3.2.1), where \( S^m = S^m(\Gamma^m) \) is the space of symmetric, tangential tensors on \( \Gamma^m \). Note that the tangent space on \( \Gamma^m \) is piecewise defined through the mesh \( \mathcal{M}_m^\Gamma \). We require a transformation rule that relates functions in \( H^4_{\Gamma}(\Gamma^m; S^m) \) to \( H^4_{\Gamma}(\Gamma^l; S^l) \) (with \( m \neq l \)), such that conormal-conormal continuity is preserved; this is crucial to ensure that the HHJ finite element space in (5.4) is continuous. We first recall the matrix Piola transform from Arnold & Walker (2020).

**Definition 4.5** (Standard Matrix Piola Transform) Let \( \Phi : \mathcal{D} \rightarrow \tilde{\mathcal{D}} \) be an orientation-preserving diffeomorphism between domains in \( \mathbb{R}^n \). Given \( \phi : \mathcal{D} \rightarrow \mathbb{R}^{n \times n} \), we define its **matrix Piola transform** \( \bar{\phi} : \tilde{\mathcal{D}} \rightarrow \mathbb{R}^{n \times n} \) by

\[
\bar{\phi}(\tilde{x}) = (\det B)^{-2} B \phi(x) B^T = (\det \nabla \phi)^{-2} (\partial \phi) \phi^T(x) (\partial \phi)^T,
\]

where \( \bar{x} = \Phi(x) \), and \( B = \nabla \phi(x) \).

Note that (4.10) is analogous to the Piola transform for \( H(\text{div}) \) functions. This suggests the following surface version.

**Definition 4.6** (Surface Matrix Piola Transform) Let \( \Gamma \) be a 2-dimensional surface that is locally parameterized by the chart \( (U, \chi) \), i.e. \( \Theta := \chi(U) \subset \Gamma \). Given the contravariant tensor \( \phi^{ab} : U \rightarrow \mathbb{S} \), we define its **extrinsic surface matrix Piola transform** \( \bar{\phi} : \Theta \rightarrow \mathbb{S} \), via the chart, by

\[
\bar{\phi}(\tilde{x}) = g^{-1} e_\alpha \phi^{\alpha \beta}(x) e_\beta,
\]

where \( \tilde{x} = \chi(x) \), \( e_\alpha := \partial_\alpha \chi \), \( g^{ab} := e_\alpha \cdot e_\beta \), and \( g := \det g^{ab} \).

Moreover, let \( J = (\nabla_{\Gamma^1} F^m_\Gamma) \bar{\mathbf{P}}_x \in \mathbb{R}^{3 \times 2} \) where \( \nabla_{\Gamma^1} \) is the surface gradient on \( T^1 \in \mathcal{J}_h^l \), \( (\nabla_{\Gamma^1} F^m_\Gamma) \in \mathbb{R}^{3 \times 2} \), and \( \bar{\mathbf{P}}_x \in \mathbb{R}^{3 \times 2} \) is the projection and restriction onto the tangent space of \( T^1 \). Given an extrinsic tensor \( \bar{\phi} : \Gamma^1 \rightarrow S^1 \) on the piecewise linear surface \( \Gamma^1 \), we map (element-wise) to a tensor \( \phi : \Gamma^m \rightarrow \mathbb{S}^m \), for any \( m \), via

\[
\phi(x) = \text{Piola}(\bar{\phi}(\tilde{x})) := \det Q^{-1} J \bar{\mathbf{P}}_x^T \bar{\phi}(\tilde{x}) \bar{\mathbf{P}}_x J^T,
\]

where \( Q = J^T J \) and \( \tilde{x} = F^m_\Gamma(\tilde{x}) \). The inverse Piola transform is given by

\[
\bar{\phi}(\tilde{x}) = \text{Piola}^{-1}(\phi(x)) := \det Q \bar{\mathbf{P}}_x Q^{-1} J^T \phi(x) J Q^{-1} \bar{\mathbf{P}}_x^T.
\]

Note that (4.11) is similar to the definition of \( S \) in (A.7), except for the \( g^{-1} \) factor.

**Remark 4.1** A tangential tensor \( \bar{\phi} \) defined on \( \Gamma^1 \) is mapped to a tensor \( \phi \) on \( \Gamma^m \), for \( m \neq l \), through the map \( \Phi^{lm} \) (see (4.2)). To see this more explicitly, suppose \( \bar{\phi} : \Gamma^l \rightarrow S^l \). Then, given a chart for one triangle \( T^l \subset \Gamma^l \), with metric \( \bar{g}_{ab}l \), there is a unique contravariant tensor \( \phi^{ab} \) such that \( \bar{\phi} \) and \( \phi^{ab} \) satisfy (4.11). Furthermore, using the chart for the corresponding triangle \( T^m \subset \Gamma^m \), there is a unique \( \bar{\phi} : \Gamma^m \rightarrow S^m \) that satisfies (4.11) with a different metric \( \bar{g}_{ab} \). We adopt this approach throughout the paper.
A simple consequence of Definition 4.6 is the following.

**Proposition 4.7** Adopt the hypothesis of Definition 4.6 and recall $F^m_T$ from Section 4.1. Let $\tilde{\mathcal{K}} := \mathcal{K}_h \setminus \mathcal{K}_T$, $\chi := \mathcal{K}_h \setminus \mathcal{K}_T$ (note that $\tilde{\mathcal{K}} = F^m_T \setminus \tilde{\mathcal{K}}$), and let $\mathbf{n}(\mathbf{h})$ be the unit conormal on $\partial T^m (\partial T^i)$; likewise, let $\mathbf{i}(\mathbf{h})$ be the unit tangent vector of $\partial T^m (\partial T^i)$. Moreover, let $\tilde{\Phi} \in H^1(\Gamma^m; S^m)$, $\Phi \in H^1(\Gamma^i; S^i)$, be related through (4.11) using $\mathcal{K}$ and $\tilde{\mathcal{K}}$. Then, denoting the surface gradient on $T^i$ by $\nabla_{T^i}$, we have

$$\tilde{\Phi}^m \circ F^m_T = \tilde{\Phi}^m \| (\nabla_{T^i} F^m_T) \mathbf{i} \|^2. \tag{4.14}$$

**Proof.** Noting $\tilde{\Phi}^m := \mathbf{n}^T \tilde{\Phi} \mathbf{n}$, $\Phi^m := \mathbf{m}^T \Phi \mathbf{m}$, and applying (A.12), gives

$$\tilde{\Phi}^m \circ \mathcal{K} = |t^\mu \tilde{e}_m|^2 n_\alpha \Phi^m n_\beta, \quad \tilde{\Phi}^m \circ \tilde{\mathcal{K}} = |\tilde{t}^\mu \tilde{e}_m|^2 n_\alpha \Phi^m n_\beta.$$

Since $\tilde{e}_m = (\nabla_{T^i} F^m_T) \tilde{e}_m$, for all $\omega$, and $\mathbf{i} = t^\mu \tilde{e}_m |t^\mu \tilde{e}_m|^{-1}$, we have $|\nabla_{T^i} F^m_T \mathbf{i}|^2 = |t^\mu \tilde{e}_m|^2 |t^\mu \tilde{e}_m|^2$. Combining these results yields the assertion. \qed

Since $F^m_T$ is piecewise smooth and continuous with respect to the mesh $\mathcal{K}_h$, it follows that $(\nabla_{T^i} F^m_T) \mathbf{i}$ is single-valued at interelement edges, so $\Phi$ is conormal-conormal continuous if and only if $\Phi$ is. So, by completion, any $\tilde{\Phi} \equiv (\tilde{\Phi}^m, \Phi^m) \in H^1_h(\Gamma^m; S^m)$ transforms to $\Phi \equiv (\tilde{\Phi}^m, \Phi^m) \in H^1(\Gamma^i; S^i)$ as follows: $\tilde{\Phi}$ and $\Phi$ are related through the Piola transform (see Remark 4.1) while $\tilde{\Phi}^m$ and $\Phi^m$ are related through (4.14). The following norm equivalence is immediate from (4.8):

$$\| \tilde{\Phi} \|_0, h, m \approx \| \Phi \|_0, h, i, \quad \forall \tilde{\Phi} \in H^1_h(\Gamma^m; S^m), \quad \text{for all } 1 \leq l, m \leq k, \infty. \tag{4.15}$$

### 4.3 Mapping Forms

The following result is essential for analyzing the geometric error when approximating the solution on an approximate domain and also for deriving the discrete inf-sup condition on curved elements.

**Theorem 4.8** Let $1 \leq l \leq k$ such that $l \leq m$, for $1 \leq m \leq k$, or $m = \infty$, and recall the mapping discussion in Section 4.1. Let $\tilde{\mathbf{\sigma}} \in H^1_h(\Gamma^m; S^m)$, $\mathbf{\sigma} \in H^1(\Gamma^i; S^i)$, and $\mathbf{\tilde{\sigma}} \in H^1_h(\Gamma^i; S^i)$ and assume they are related through (4.11) in the sense of Remark 4.1. Make the same assumption for $\tilde{\Phi}$, $\Phi$, $\Phi$. In addition, let $v \in H^1_h(\Gamma^m)$, $\tilde{v} \in H^1_h(\Gamma^i)$, $v \in H^1(\Gamma^i)$, where $\tilde{v} \circ \Phi^m = \tilde{v}$ and $v \circ \Phi^i = v$. Then, there holds

$$a^m(\tilde{\mathbf{\sigma}}, \tilde{\Phi}) = a^i(\tilde{\mathbf{\sigma}}, \Phi) + O(h^i)\| \tilde{\mathbf{\sigma}} \|_{L^2(\Gamma^i)} \| \Phi \|_{L^2(\Gamma^i)}, \tag{4.16}$$

$$b^m(\tilde{\Phi}, v) = b^i(\Phi, v) + O(h^i)\| \tilde{\Phi} \|_{0, h, i} \left( \| v \|_{0, h, i} + \| v \|_{H^1(\Gamma^i)} \right)$$

$$- b^i(\Phi, (F^m - F^i) \cdot P_0 \nabla_{T^i} \tilde{v}) + \sum_{E^i \in \gamma^1_h} \left( \tilde{\Phi}^m, F^i \cdot \nabla_{T^i} \tilde{v} \right)_{E^i}, \tag{4.17}$$

where $\gamma^1_h$ is the Lagrange interpolation operator onto piecewise linear operators on $\Gamma^i$, $P_0 : L^2(\Gamma^i) \to L^2(\Gamma^i)$ is the projection onto piecewise constants, and $\beta = |(\mathbf{i} - \tilde{\mathbf{i}}) \times \mathbf{v}| \cdot \mathbf{i}$, $| \beta | = O(h^i)$, and $\tilde{v} = v \circ F^i$ is the unit normal vector of $T^i$ (see Theorem 4.1).

**Proof.** From (3.9), we have $a^m(\tilde{\mathbf{\sigma}}, \tilde{\Phi}) = (\mathbf{K} \tilde{\mathbf{\sigma}}, \tilde{\Phi})_{T^m} = \sum_{T^m \in \mathcal{K}_h} (\mathbf{K} \tilde{\mathbf{\sigma}}, \tilde{\Phi})_{T^m}$. Consider a single element $T^m$, the map $F^m_T$, and associated element $T^i$. Now apply a global rigid motion that maps $T^m$ to $T^m$ and $T^i$ to $T^i$ such that $T^i \subset \mathbb{R}^2$. Moreover, let $\tilde{\mathbf{\sigma}}', \Phi'$ be the corresponding mapped tensors using (4.10). Clearly, from (2.4), $(\mathbf{K} \tilde{\mathbf{\sigma}}', \tilde{\Phi}')_{T^m} = (\mathbf{K} \tilde{\mathbf{\sigma}}', \tilde{\Phi}')_{T^m}$. Let $F^m_T : T^i \to T^m$ be the corresponding rotated map,
which can be viewed as a parametrization of $T^{m'}$ (see Appendix A.3 for more details). For ease of notation, let us momentarily drop the ' notation.

Treating $F^m_{T'}$ as a parametrization, (4.11) implies

$$(K \tilde{\sigma}, \tilde{\phi})_{Tm} = \left(\tilde{g}^{-3/2} \tilde{K}_{\alpha\beta} \tilde{\sigma}^{\alpha\beta}, \tilde{\phi}^{\gamma_0}\right)_{T^1},$$

(4.18)

where $K_{\gamma_0\alpha\beta} = D^{-1}[(1 - \zeta)^{-1} \tilde{g}_{\gamma_0\alpha\beta} - \zeta(1 - \zeta)^{-1} \tilde{g}_{\gamma_0\alpha\beta}]$, with the metric given by $\tilde{g}_{\alpha\beta} \equiv \tilde{g} = \tilde{J}^T \tilde{J}$, where $\tilde{J}$ is the $3 \times 2$ Jacobian matrix given by $\tilde{J} = [\partial_1 F^m_T, \partial_2 F^m_T]$. Similarly, $(K \tilde{\sigma}, \tilde{\phi})_{Tl} = \left(\tilde{g}^{-3/2} \tilde{K}_{\alpha\beta} \tilde{\sigma}^{\alpha\beta}, \tilde{\phi}^{\gamma_0}\right)_{T^1},$

where $\tilde{g}, \tilde{K}_{\gamma_0\alpha\beta}$ come from using $F^l_T$. We then arrive at

$$|\langle (K \tilde{\sigma}, \tilde{\phi})_{Tm} - (K \tilde{\sigma}, \tilde{\phi})_{Tl} \rangle| \leq C h^l \|\tilde{\phi}\|_{L^2(T^{l})} \|\tilde{\phi}\|_{L^2(T^{m})},$$

(4.19)

where we used that $|\tilde{K}_{\gamma_0\alpha\beta} - \tilde{K}_{\gamma_0\alpha\beta}|_{L^2(T^{l})} \leq C h^l$, which follows from (4.3). Since (4.19) also holds for the unrotated elements, summing over all elements yields (4.16).

As for (4.17), we start with (3.8) and write it as

$$b^m_{\gamma_0} (\tilde{\phi}, \tilde{v}) = \sum_{T_{m' \in} \mathcal{F}_h^m} \left[ \langle \tilde{\phi}, \nabla \nabla_{T' \gamma_0} \tilde{v} \rangle_{T_{m'}} - \langle \tilde{\phi}^{m' \cdot} \tilde{n} \cdot \nabla_{T' \gamma_0} \tilde{v} \rangle_{T_{m'}} \right],$$

(4.20)

noting that $\tilde{n}^T \tilde{\phi} \equiv \tilde{\phi}^{m' \cdot}$. We proceed as before, i.e. consider a single element $T^{m}$, the map $F^m_T$, and associated element $T^1$. Again, we apply a global rotation and drop the ' notation. Mapping the first term in (4.20) from $T^{m}$ to $T^{l}$, we see that

$$(\tilde{\phi}, \nabla \nabla_{T' \gamma_0} \tilde{v})_{T_{m'}} = \left(\tilde{g}^{-1/2} \tilde{\phi}^{\alpha\beta}, \left[\partial_{\alpha} \partial_{\beta} \tilde{v} - \partial_{\gamma} \Gamma_{\alpha\beta}^{\gamma} \right] \right)_{T^1},$$

(4.21)

where $\tilde{\Gamma}_{\alpha\beta}^{\gamma}$ are the Christoffel symbols of the second kind (depending on the induced metric $\tilde{g}$). By using the parametrization, we have $\tilde{\Gamma}_{\alpha\beta}^{\gamma} = \left(\tilde{g}^{-1/2} \tilde{J} \mathbf{a}_i\right)^{\gamma} \partial_{\alpha} \partial_{\beta} (F^m_{T'} \cdot \mathbf{a}_i)$, where $\tilde{g}^{\alpha\beta}$ is the inverse metric, and $\{\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3\}$ are the canonical basis vectors in $\mathbb{R}^3$. Using the estimates in (4.3) for $F^m_{T'}$, we can express (4.21) as

$$\left(\tilde{\phi}, \nabla \nabla_{T' \gamma_0} \tilde{v} \right)_{T_{m'}} = \left(\tilde{g}^{-1/2} \tilde{\phi}^{\alpha\beta}, \partial_{\alpha} \partial_{\beta} \tilde{v} \right)_{T^1} + \left(\tilde{g}^{-1/2} - 1 \right) \tilde{\phi}^{\alpha\beta}, \partial_{\alpha} \partial_{\beta} \tilde{v}\right)_{T^1}

- \left(\tilde{g}^{-1/2} \mathbf{a} \cdot \nabla_{\gamma} \tilde{\Gamma}_{\alpha\beta}^{\gamma} \right) \partial_{\alpha} \partial_{\beta} (F^m_{T'} \cdot \mathbf{a}_i) \right)_{T^1},$$

(4.22)

where we introduced $\tilde{\Gamma}_{\alpha\beta}^{\gamma} = \tilde{g}^{-1/2} \left(\tilde{g}^{-1/2} \tilde{J} \mathbf{a}_i\right)^{\gamma} \partial_{\alpha} \partial_{\beta} \left(\tilde{g}^{-1/2} \tilde{J} \mathbf{a}_i\right)$ and $\delta i^1 = 1$ if $i = \gamma$ and zero otherwise for $1 \leq \gamma \leq 2, 1 \leq i \leq 3$. A similar result holds for $\langle \phi, \nabla \nabla_{T' \gamma_0} \tilde{v} \rangle_{T_{m'}}$ by replacing $m$ with $l$ in (4.22), and replacing $\tilde{g}$ with $\tilde{J} = \tilde{J} \tilde{J}$, for $\tilde{J} = [\partial_1 F^m_T, \partial_2 F^m_T]$.

Next, let $A_1 := \left(\tilde{\phi}, \nabla \nabla_{T' \gamma_0} \tilde{v} \right)_{T_{m'}} - \left(\tilde{\phi}, \nabla \nabla_{T' \gamma_0} \tilde{v} \right)_{T_{l'}}$ and expand:

$$A_1 = -\left(\tilde{\phi}^{\alpha\beta}, \partial_{\gamma} \tilde{\Gamma}_{\alpha\beta}^{\gamma} \right) \partial_{\alpha} \partial_{\beta} (F^m_{T'} \cdot \mathbf{a}_i) \right)_{T^1} + \left(\tilde{g}^{-1/2} - 1 \right) \tilde{\phi}^{\alpha\beta}, \partial_{\alpha} \partial_{\beta} \tilde{v}\right)_{T^1}

- \left(\tilde{g}^{-1/2} \mathbf{a} \cdot \nabla_{\gamma} \tilde{\Gamma}_{\alpha\beta}^{\gamma} \right) \partial_{\alpha} \partial_{\beta} (F^m_{T'} \cdot \mathbf{a}_i) \right)_{T^1},$$

(4.23)

Note that $||\tilde{g}^{-1/2} - 1||_{L^2(T^1)} \leq C h^l$, $||\tilde{\Gamma}_{\alpha\beta}^{\gamma}||_{L^2(T^1)} \leq C h^l$, and $||\tilde{\Gamma}_{\alpha\beta}^{\gamma}||_{L^2(T^1)} \leq C h^l$, for all $T^1 \in \mathcal{F}_h^1$ using (4.3). Thus, the last three terms in (4.23) are $O(h^l)\|\tilde{\phi}\|_{L^2(T^1)}\|\nabla \nabla_{T' \gamma_0} \tilde{v} \|_{H^1(T^1)}$. Furthermore,
letting \( Q_{\alpha\beta}^T := \delta^T_{\alpha\beta} \partial_\alpha \partial_\beta (|F_{\alpha\beta}^T - F_T^I| \cdot a_\alpha) \), and using the piecewise projection \( P_0|_{T^1} : L^2(T^1) \rightarrow \mathbb{R} \) onto constants, we have that

\[
\left( \tilde{\phi}^T_{\alpha\beta} \partial_\alpha \tilde{v}^T, Q_{\alpha\beta}^T \right)_{T^1} = \left( \tilde{\phi}^T_{\alpha\beta} P_0 \partial_\alpha \tilde{v}, Q_{\alpha\beta}^T \right)_{T^1} + \left( \tilde{\phi}^T_{\alpha\beta} [\partial_\beta \tilde{v} - P_0 \partial_\beta \tilde{v}], Q_{\alpha\beta}^T \right)_{T^1} + Ch \| \tilde{\phi}^T_{\alpha\beta} \|_{L^2(T^1)} \| \nabla_{T^1} \tilde{v} \|_{H^1(T^1)},
\]

where we used the approximation property of \( P_0 \), and \( \| Q_{\alpha\beta}^T \|_{L^\infty(T^1)} \leq Ch^{-1} \), for all \( T^1 \in \mathcal{T}_h \). Note that

\[
\left( \tilde{\phi}^T_{\alpha\beta} P_0 \partial_\alpha \tilde{v}, Q_{\alpha\beta}^T \right)_{T^1} = \left( \tilde{\phi} \nabla_{T^1} [(F_{\alpha\beta}^T - F_T^I) \cdot P_0 \nabla_{T^1} \tilde{v}] \right)_{T^1},
\]

and the same result holds in the unrotated coordinates. Therefore,

\[
\left( \tilde{\phi}, \nabla_{T^1} \tilde{v} \right)_{T^1} = \left( \tilde{\phi}, \nabla_{T^1} \tilde{v} + O(h^l) \right) \| \tilde{\phi}^T \|_{L^2(T^1)} \| \nabla_{T^1} \tilde{v} \|_{H^1(T^1)} - \left( \tilde{\phi}, \nabla_{T^1} [(F_{\alpha\beta}^T - F_T^I) \cdot P_0 \nabla_{T^1} \tilde{v}] \right)_{T^1}.
\]

Next, consider the second term in (4.20). Again, we focus on a single element \( T^m \), map it to \( T^1 \), and apply a global rotation to obtain \( T^{m'} \) and \( T^{l'} \subset \{ x_3 = 0 \} \). Let \( \tilde{t}, \tilde{n} \in \mathbb{R}^3 \) be the oriented unit tangent and conormal vectors of \( \partial T^{l'} \) which point in the plane \( \{ x_3 = 0 \} \). It behooves us to introduce \( F_{\alpha}^{T} = [I_2, 0] \) so that \( \tilde{F}_{\alpha}^{T} \tilde{n} \in \mathbb{R}^2 \) and we drop the \( ' \) notation for simplicity.

Let \( \tilde{n} \) be the conormal of \( \partial T^{m'} \), and let us abuse notation with \( \tilde{n} \equiv \tilde{n} \circ F_{\alpha}^{T} \). By (4.14), \( \tilde{\phi}^m \circ F_{\alpha}^{T} = \tilde{\phi}^m [\tilde{J}^T]^{-2} \); note that the arc-length measure on \( \partial T^{m'} \) is given by \( ds(\tilde{g}) = |\tilde{J}|d\tilde{s} \), where \( d\tilde{s} \) is the arc-length measure on \( \partial T^{l'} \). Applying a change of variable yields

\[
\langle \tilde{\phi}^m, \tilde{n} \cdot \nabla_{T^1} \tilde{v} \rangle_{T^{m'}} = \left( |\tilde{J}|^{-1} \tilde{\phi}^m, \tilde{n} \cdot \tilde{J}^T \tilde{g}^{-1} \tilde{F}^T \nabla_{T^1} \tilde{v} \right)_{T^{l'}}.
\]

where we used (4.14), (A.8), and \( \nabla_{T^1} \tilde{v} \in \mathbb{R}^3 \). A similar result holds for \( \langle \tilde{\phi}^m, \tilde{n} \cdot \nabla_{T^1} \tilde{v} \rangle_{T^{l'}} \) by replacing \( m \) with \( l \) in (4.26), and replacing \( \tilde{g} \) with \( \tilde{g} \), etc.

Define \( A_2 := \langle \tilde{\phi}^m, \tilde{n} \cdot \nabla_{T^1} \tilde{v} \rangle_{T^{m'}} - \langle \tilde{\phi}^m, \tilde{n} \cdot \nabla_{T^1} \tilde{v} \rangle_{T^{l'}} \) and expand:

\[
A_2 = \left( (|\tilde{J}|^{-1} - |\tilde{J}^T|^{-1}) \tilde{\phi}^m, \tilde{n} \cdot \nabla_{T^1} \tilde{v} \right)_{\partial T^{l'}} + \left( (|\tilde{J}|^{-1} - |\tilde{J}^T|^{-1}) \tilde{\phi}^m, \tilde{n} \cdot \tilde{J}^T \tilde{g}^{-1} \tilde{F}^T \nabla_{T^1} \tilde{v} \right)_{\partial T^{l'}}
\]

\[
+ \left( (|\tilde{J}|^{-1} - 1) \tilde{\phi}^m, \tilde{z}^T \nabla_{T^1} \tilde{v} \right)_{\partial T^{l'}} + \left( \tilde{\phi}^m, \tilde{z}^T \nabla_{T^1} \tilde{v} \right)_{\partial T^{l'}}^T,
\]

where \( \mathbb{R}^3 \ni \tilde{z}^T = \tilde{n}^T \tilde{J} \tilde{g}^{-1} \tilde{F}^T - \tilde{h}^T \tilde{J} \tilde{g}^{-1} \tilde{F}^T \). Let \( \alpha = |\tilde{J}|^{-1} - |\tilde{J}^T|^{-1} \) and note that from (4.3), \( |\alpha| = O(h^l) \) and \( |||\tilde{J}|^{-1} - 1|| = O(h^l) \). Using (A.15), we get

\[
A_2 = \left\langle \alpha \tilde{\phi}^m, \tilde{n} \cdot \nabla_{T^1} \tilde{v} \right\rangle_{\partial T^{l'}} + \left( h^l \right) \| \tilde{\phi}^m \|_{L^2(\partial T^{l'})} \| \nabla_{T^1} \tilde{v} \|_{L^2(\partial T^{l'})}
\]

\[
+ \left( \tilde{\phi}^m, \tilde{h} \cdot \nabla_{T^1} \tilde{v} \right)_{\partial T^{l'}} - \left( \tilde{\phi}^m, \tilde{n} \cdot \nabla_{T^1} (F_{\alpha}^{T} - F_{\alpha}^{T}) \cdot \nabla_{T^1} \tilde{v} \right)_{\partial T^{l'}}^T,
\]

where \( \beta \) was defined earlier. By the approximation properties of \( \mathcal{T}_h \), and using (3.2), we have

\[
h^{1/2} \| \nabla_{T^1} \tilde{v} - \nabla_{T^1} \tilde{J} \tilde{g}^{-1} \tilde{v} \|_{L^2(\partial T^{l'})} \leq C \left( \| \nabla_{T^1} (\tilde{v} - \tilde{J} \tilde{g}^{-1} \tilde{v}) \|_{L^2(\partial T^{l'})} \right.
\]

\[
+ h \| \nabla_{T^1} (\tilde{v} - \tilde{J} \tilde{g}^{-1} \tilde{v}) \|_{L^2(\partial T^{l'})} \right) \leq Ch \| \nabla_{T^1} \tilde{v} \|_{L^2(\partial T^{l'})}.
\]
and similarly \( h^{1/2} \| \nabla v - P_0 \nabla v \|_{L^2(\partial T^1)} \leq C h \| \nabla v \|_{L^2(T^1)}. \) Applying (3.2) to \( \| \nabla v \|_{L^2(\partial T^1)} \) in (4.28) and combining with the above estimates yields

\[
A_2 = \left( \alpha \phi^m_\nu \cdot \nabla v \right)_{\partial T^1} + O(h') \| \phi^m_\nu \|_{L^2(\partial T^1)} \| \nabla v \|_{H^1(T^1)}
+ \left( \phi^m_\nu, \beta \tilde{I} \cdot \nabla v, \mathcal{F}_h^{1/1} v \right)_{\partial T^1} - \left( \phi^m_\nu, \beta \tilde{I} \cdot \nabla (F^n - F^n_0 \cdot P_0 \nabla v) \right)_{\partial T^1}. \tag{4.30}
\]

This estimate also holds for the unrotated element, and for all \( T^1 \in \mathcal{T}_h^1 \).

Now note that the mapped tangent vectors, and the mapped normal vector \( \nu \), are continuous across edges in \( \mathcal{E}_h^1 \), which implies that \( \alpha \) and \( \beta \) are continuous across edges. Since \( \phi^m_\nu \) is also continuous, and setting \( \alpha_{E^1} := \alpha_{E^1} \), this implies that

\[
\sum_{T^1 \in \mathcal{T}_h^1} \left( \alpha \phi^m_\nu \cdot \nabla v \right)_{\partial T^1} = \sum_{E^1 \in \mathcal{E}_h^1} \left( \alpha_{E^1} \phi^m_\nu \cdot \nabla v \right)_{E^1} + \sum_{E^1 \in \mathcal{E}_h^1} \left( \phi^m_\nu, \beta \tilde{I} \cdot \nabla v, \mathcal{F}_h^{1/1} v \right)_{E^1} \tag{4.31}
\]

where the internal edge terms in the second sum cancel out. Combining the above results and summing over all \( T^m \in \mathcal{T}_h^m \) proves (4.17).

A simple consequence of Theorem 4.8 is

\[
b^{m}_h(\Phi, v) = b^{m}_h(\Phi, \tilde{v}) + O(h^{-1/2}) | \Phi |_{0,2,h} \| \tilde{v} \|_{2,0,h}. \tag{4.32}
\]

5. Finite Element Approximation

5.1 Curved Lagrange Spaces

Let \( r \geq 0 \) be an integer and \( m \geq 1 \) be an integer or \( \infty \). The (continuous) Lagrange finite element space of degree \( r+1 \) is defined on \( T^m \) via the mapping \( F^m_T \):

\[
W^m_h \equiv W^m_h(T^m) := \{ v \in H^2(T^m) \mid v \circ F^m_T \in \mathcal{P}_{r+1}(T^1), \forall T \in \mathcal{T}_h^m \}. \tag{5.1}
\]

For the case \( m = \infty \) (the exact domain) we simply write \( W_h \). Again, owing to the continuous embedding \( H^2(T^1) \hookrightarrow C^0(T^1) \) (see (4.6)), we can define the Lagrange interpolation operator \( \mathcal{I}^*_h : H^2(T^1) \rightarrow W^1_h \) Babuška et al. (1980) defined on each element \( T^1 \in \mathcal{T}_h^1 \) by

\[
(\mathcal{I}^*_h v)(x) - v(x) = 0, \quad \forall \text{ vertices } x \text{ of } T^1,
\]

\[
\int_{E^1} (\mathcal{I}^*_h v - v) q ds = 0, \quad \forall q \in \mathcal{P}_{r-1}(E^1), \forall E^1 \in \partial T^1,
\]

\[
\int_{T^1} (\mathcal{I}^*_h v - v) q dS = 0, \quad \forall q \in \mathcal{P}_{r-2}(T^1). \tag{5.2}
\]

Then, given \( v \in H^2(T^m) \), we define the global interpolation operator, \( \mathcal{I}_h^m : H^2(T^m) \rightarrow W^m_h \), element-wise through \( \mathcal{I}_h^m v |_{T^m} \circ F^m_T := \mathcal{I}^*_h v \circ F^m_T \). Note that \( v \circ F^m_T \in C^0(T^1) \) because \( v \in C^0(T^m) \) and \( F^m_T \) is continuous over \( T^1 \). The approximation properties of \( \mathcal{I}_h^m \) are standard. We also denote \( \mathcal{I}_h^{m,s} \) to be the above Lagrange interpolant on \( T^m \) onto continuous piecewise polynomials of degree \( s \), and we make the following abbreviation \( \mathcal{I}_h^{m,r+1} \equiv \mathcal{I}_h^m \).
5.2 The HHJ Curved Finite Element Space

We start with a space of tangential, tensor-valued functions defined on curved surfaces, with special continuity properties and state the conforming finite element space $V_h^m$ for $H^1_h(\Gamma^m; S^m)$ in (3.10), where $S^m = S^m(\Gamma^m)$ is the space of symmetric, tangential tensors on $\Gamma^m$. In addition, we define an interpolation operator for this space while accounting for the effect of curved surface elements.

For $p > 3/2$, let

$$\mathcal{M}_m^s(\Gamma^m) := \{ \varphi \in L^2(\Gamma^m; S^m) \mid \varphi|_{\Gamma^m} \in W^{1,p}(\Gamma^m; S^m) \forall \Gamma^m \in \mathcal{T}_h^m, \text{ with } \varphi \text{ conormal-conormal continuous} \}. \quad (5.3)$$

where the conormal-conormal continuity condition holds at inter-element boundaries, i.e. for any pair of triangles $(T^m_a, T^m_b)$ that share an edge $E^m = T^m_a \cap T^m_b$, we have $n^m_a \varphi n|_{E^m} = n^m_b \varphi n|_{E^m}$, where $n_a(n_b)$ is the conormal of $\partial T^m_a(\partial T^m_b)$; note that, in general, $n_a \neq -n_b$ unless $m = \infty$. Clearly, $\mathcal{M}_m^s(\Gamma^m) \subset H^1_h(\Gamma^m; S^m)$ with $\varphi_m = n^r \varphi n$ on each mesh edge. We assume $p > 3/2$ for simplicity to ensure that the trace of a function in $\mathcal{M}_m^s(\Gamma^m)$ onto the mesh skeleton $\partial^m_\Gamma$ is in $L^2(\partial^m_\Gamma)$.

We can use (4.11) to build the global, conforming, HHJ finite element space (on curved elements) by mapping from a reference element (see Section 4.2 for details), i.e., $V_h^m \equiv V_h^m(\Gamma^m) \subset \mathcal{M}_m^s(\Gamma^m)$ is defined by

$$V_h^m(\Gamma^m) := \{ \varphi \in \mathcal{M}_m^s(\Gamma^m) \mid \varphi|_{\Gamma^m} \in \mathcal{P}_s(1,1; S^1), \forall \Gamma^m \in \mathcal{T}_h^m \}, \quad (5.4)$$

using the Piola transform in (4.12). Note that $V_h^m$ is isomorphic to $V_h^1$, for $1 \leq m \leq k$ and $m = \infty$. Note that, by (3.2) and an inverse inequality, we have the following equivalence

$$||\varphi||_{0,h,m} \approx ||\varphi||_{L^2(\Gamma^m)}, \forall \varphi \in V_h^m. \quad (5.5)$$

Next, we define the following tensor-valued interpolation operator $\Pi^1_h : \mathcal{M}_m^s(\Gamma^m) \rightarrow V_h^1$ Brezzi & Raviart (1976); Babuška et al. (1980) defined on each element $T^1 \in \mathcal{T}_h^1$ by

$$\int_{E^1} n^T \left[ \Pi^1_h \varphi - \varphi \right] n q d s = 0, \quad \forall q \in \mathcal{P}_s(E^1), \forall E^1 \in \partial T^1, \quad (5.6)$$

$$\int_{T^1} \left[ \Pi^1_h \varphi - \varphi \right] : \eta d S = 0, \quad \forall \eta \in \mathcal{P}_{r-1}(1,1; S).$$

Recall Theorem 4.8 and Definition 4.6. Given $\varphi \in \mathcal{M}_m^s(\Gamma^m)$, we define the global interpolation operator, $\Pi^m_h : \mathcal{M}_m^s(\Gamma^m) \rightarrow V_h^m$, element-wise through

$$\Pi^m_h \varphi|_{\Gamma^m} \cdot F^m_T = \Pi^1_h \varphi(\tilde{x}), \text{ with } x = F^m_T(\tilde{x}), \quad (5.7)$$

where $\varphi(\tilde{x}) := \Pi^1_h(\varphi)(x)$ (i.e. see (4.13)). The operator $\Pi^m_h$ clearly extends to $H^1_h(\Gamma^m; S^m)$, as well as $W^{1,p}(\Gamma^m; S^m)$, and satisfies many basic approximation results which can be found in (Arnold & Walker, 2020, Supp. Mater.). Note that the Degrees-of-Freedom (DoFs) for $V_h^m$ are given by (5.6) (Brezzi & Raviart, 1976, Lem. 3), Li (2018).

On affine elements, we have a Fortin like property involving $b^i_h(\cdot, \cdot)$ Brezzi & Raviart (1976); Babuška et al. (1980); Blum & Rannacher (1990):

$$b^i_h(\varphi - \Pi^1_h \varphi, \eta_h) = 0, \quad \forall \varphi \in H^0(\Gamma^1; S^1), \quad \forall \eta_h \in W^1_h,$$

$$b^i_h(\varphi_h, \eta - \mathcal{S}^1_h \eta) = 0, \quad \forall \varphi_h \in V^1_h, \quad \forall \eta \in H^2(\Gamma^1), \quad (5.8)$$
which holds for any piecewise constant function \( \theta_h \) defined on \( \mathcal{S}_h \) Brezzi & Raviart (1976); Babuška et al. (1980); Blum & Rannacher (1990). However, (5.8) does not hold on curved elements, but instead we have the following result.

**Lemma 5.1** Let \( 1 \leq m \leq k \), or \( m = \infty \), and set \( r \geq 0 \) to be the degree of HHJ space \( V_h^m \), and \( r + 1 \) to be the degree of the Lagrange space \( W_h^m \). Moreover, assume \( V_h^m \) and \( W_h^m \) impose no essential boundary conditions. Then, the following estimates hold:

\[
\begin{align*}
|b_h^m(\varphi_h, v - \mathcal{S}_h^m v)| &\leq C||\varphi_h||_{L^2(\Gamma^m)} \left( ||\nabla \Gamma^m (v - \mathcal{S}_h^m v)||_{L^2(\Gamma^m)} + h||\nabla \Gamma^m (v - \mathcal{S}_h^m v)||_{L^2(\mathcal{S}_h^m)} \right), \\
|b_h^m(\varphi - \Pi_h^m \varphi, v_h)| &\leq C||\varphi - \Pi_h^m \varphi||_{H^1_0(\Gamma^m)} ||\nabla \Gamma^m v_h||_{L^2(\Gamma^m)},
\end{align*}
\]

for all \( \varphi \in H_0^0(\Gamma^m; S^m) \), \( v_h \in W_h^m \), and all \( \varphi_h \in V_h^m \), \( v \in H_0^1(\Gamma^m) \), where \( C \) is an independent constant. Note that \( C = 0 \) if \( m = 1 \).

**Proof.** The result follows by setting \( l = 1 \) in (4.17), using (4.3) and (5.8), and equivalence of norms. In other words, for the first estimate in (5.9), replace \( v \) with \( v - \mathcal{S}_h^m v \) in (4.17), set \( \varphi = \varphi_h \in V_h^m \), use (5.8), and (5.5) to get

\[
|b_h^m(\varphi_h, v - \mathcal{S}_h^m v)| \leq C||\varphi_h||_{L^2(\Gamma^m)} \left( ||\nabla \Gamma^m (v - \mathcal{S}_h^m v)||_{L^2(\Gamma^m)} + h||\nabla \Gamma^m (v - \mathcal{S}_h^m v)||_{L^2(\mathcal{S}_h^m)} \right),
\]

then use equivalence of norms: (4.9), (4.15). For the second estimate, replace \( \varphi \) with \( \varphi - \Pi_h^m \varphi \) in (4.17), set \( v = v_h \in W_h^m \), use (5.8), and an inverse inequality to get

\[
|b_h^m(\varphi - \Pi_h^m \varphi, v_h)| \leq C||\varphi - \Pi_h^m \varphi||_{H^1_0(\Gamma^m)} ||\nabla \Gamma^1 \varphi_h||_{L^2(\Gamma^m)},
\]

followed by equivalence of norms. \( \square \)

### 5.3 The HHJ Mixed Formulation

We pose (3.10) on \( \Gamma^m \) with continuous skeleton spaces denoted \( \mathcal{V}_h^m = \mathcal{V}_h^m(\Gamma^m) \) and \( \mathcal{W}_h^m = \mathcal{W}_h^m(\Gamma^m) \). Fixing the polynomial degree \( r \geq 0 \), the conforming finite element spaces are

\[
V_h^m \subset \mathcal{V}_h^m, \quad W_h^m \subset \mathcal{W}_h^m,
\]

where we abuse notation by now enforcing essential boundary conditions directly in the definitions of \( V_h^m \) and \( W_h^m \). The conforming finite element approximation to (3.10) is as follows. Given \( f \in H^{-1}(\Gamma^m) \), find \( \sigma_h \in V_h^m \), \( w_h \in W_h^m \) such that

\[
\begin{align*}
a^m(\sigma_h, \varphi) + b_h^m(\varphi, w_h) &= 0, \quad \forall \varphi \in V_h^m, \\
b_h^m(\sigma_h, v) &= -(f, v)_{\Gamma^m}, \quad \forall v \in W_h^m.
\end{align*}
\]

The well-posedness of (5.13) is established in the next section, i.e., we prove the classic LBB conditions Boffi et al. (2013). With this, we have the following a priori estimate:

\[
\|w_h\|_{2,h,m} + ||\sigma_h||_{0,h,m} \leq C\|f\|_{H^{-1}(\Gamma^m)}.
\]

Note that LBB conditions for (5.13), for the case \( m = 1 \), was originally shown in Blum & Rannacher (1990) for flat domains.
5.3.1 Well-posedness. Obviously, we have

\[ a^m(\sigma, \varphi) \leq A_0 \| \sigma \|_{L^2(\Gamma_m)} \| \varphi \|_{L^2(\Gamma_m)} \], \quad \| b^m_h(\varphi, \nu) \| \leq B_0 \| \nu \|_{0,h,m} \| \nu \|_{2,h,m}, \]

(5.15)

for all \( \sigma, \varphi \in H^1_0(\Gamma^m; S) \supset V^m_h, \nu \in H^2_0(\Gamma^m) \supset W^m_h \), and we have coercivity of \( a^m(\cdot, \cdot) \), which is a curved element version of (Babuška et al., 1980, Thm. 2).

**Lemma 5.2** Assume the domain \( \Gamma^m \) is piecewise \( C^{k+1} \) consisting of curved elements as described in Section 4. Then there is a constant \( \alpha_0 > 0 \), independent of \( h \) and \( m \), such that

\[ a^m(\sigma, \sigma) \geq \min(\| K \|) \| \sigma \|_{L^2(\Gamma_m)}^2 \geq \alpha_0 \| \sigma \|_{0,h,m}^2, \quad \forall \sigma \in V^m_h, \forall h > 0, \]

(5.16)

where \( \alpha_0 \) depends on \( K \).

**Proof.** Clearly, \( a^m(\sigma, \sigma) \geq C_0 \| \sigma \|_{L^2(\Gamma_m)}^2 \), where \( C_0 \) depends on \( K_{\gamma\alpha\beta} \). Furthermore, by (5.5), \( \| \sigma \|_{L^2(\Gamma_m)} \geq C^{-1} \| \sigma \|_{0,h,m} \), so then \( \alpha_0 := C_0/C^2 \).

5.3.2 Inf-Sup. The stability of the surface HHJ method, as well as its convergence, depends crucially on the following choice of surface approximation: let \( F^m_T : T^1 \rightarrow T^m \), for all \( T^1 \in \mathcal{T}_h^1 \) and \( 1 \leq m \leq k \), be given by

\[ F^m_T \equiv \tilde{F}^m_T := \mathcal{F}_h^{1,m} F_T \equiv \mathcal{F}_h^{1,m} \Psi_T, \]

(5.17)

where \( \mathcal{F}_h^{1,m} \) is the Lagrange interpolation operator in (5.2) onto degree \( m \) polynomials; we simplify the notation by writing \( F^m_T \equiv \tilde{F}^m_T \). This choice is necessary to guarantee optimal convergence of the HHJ method when \( m = r + 1 \). If \( m > r + 1 \), the standard Lagrange interpolant can be used.

Next, we have a surface finite element version of the inf-sup condition in (Blum & Rannacher, 1990, Lem. 5.1).

**Lemma 5.3** Assume the surface \( \Gamma^m \subset \mathbb{R}^3 \), with \( 1 \leq m \leq k \) or \( m = \infty \) consists of curved elements as described in Section 4 and satisfying (5.17). Then, for any degree \( r \geq 0 \), there is a constant \( \beta_0 > 0 \), independent of \( h \) and \( m \), such that for all \( h \) sufficiently small,

\[ \sup_{\varphi \in V^m_h} \frac{|b^m_h(\varphi, \nu)|}{\| \varphi \|_{0,h,m}} \geq \beta_0 \| \nu \|_{2,h,m}, \quad \forall \nu \in W^m_h, \forall h > 0. \]

(5.18)

**Proof.** We start with the case \( m = 1 \), which is addressed in Lemma A.3:

\[ \sup_{\varphi \in V^1_h} \frac{|b^1_h(\varphi, \bar{\nu})|}{\| \bar{\nu} \|_{0,h,1}} \geq C_0 \| \bar{\nu} \|_{2,h,1}, \quad \forall \bar{\nu} \in W^1_h, \forall h > 0, \]

(5.19)

on the piecewise linear domain \( \Gamma^1 \) with triangulation \( \mathcal{T}_h^1 \), and holds for any degree \( r \geq 0 \) of the HHJ space.

Next, we recall the mapped variables introduced in Theorem 4.8. Because of boundary conditions, the choice of surface parametrization (5.17), and the Fortin property (5.8), the identity (4.17) reduces to

\[ b^m_h(\bar{\varphi}, \bar{\nu}) = b^1_h(\bar{\varphi}, \bar{\nu}) + O(h) \| \bar{\varphi} \|_{0,h,1} \left( \| \bar{\nu} \|_{2,h,1} + |\bar{\nu}|_{H^1(\Gamma^1)} \right), \]

(5.20)
where we set \( l = 1 \). From (4.15), we have that \( \| \hat{\varphi} \|_{0,h,1} \approx \| \hat{\varphi} \|_{0,h,m} \). Then, combining (4.7) with (5.20), we get

\[
\frac{|b_h^m(\hat{\varphi},\tilde{v})|}{\| \hat{\varphi} \|_{0,h,m}} \geq C_1 \frac{|b_h^1(\hat{\varphi},\tilde{v})|}{\| \hat{\varphi} \|_{0,h,1}} - C_1 h \| \tilde{v} \|_{2,h,1}.
\]  

(5.21)

Taking the supremum, using (5.19), and the equivalence of norms (4.9), proves (5.18) when \( h \) is sufficiently small. \( \square \)

**Remark 5.1** By (4.7), (5.18) holds with \( \| v \|_{2,h,m} \) replaced by \( \| v \|_{H^1(\Gamma^m)} \) with a different inf-sup constant.

Therefore, (5.15), (5.16), and (5.18) imply by the standard theory of mixed methods that (5.13) is well-posed in the mesh dependent norms.

### 6. Error Analysis

We prove convergence of the surface HHJ method while accounting for the approximation of the surface using curved elements (see Section 4). The main difficulties are dealing with higher derivatives of the nonlinear map and handling the jump terms in the mesh dependent norms when affected by a nonlinear map. The key ingredients here are Theorem 4.1, (5.8), and (5.17).

In deriving the error estimates, we make the following regularity hypothesis, which assumes the Kirchhoff plate regularity for the flat domains (taken from (Blum & Rannacher, 1990, Thm. 2), (Blum & Rannacher, 1990, Table 1)) also applies to the surface case.

**Hypothesis 1 (regularity)** Given \( t \in [3,\infty) \), assume \( \Gamma \) satisfies the assumptions in Section 3.1, with \( k \geq t - 1 \), and let \( f \in H^{-1}(\Gamma) \). Then the weak solution \( w \in \mathcal{W} \) of (2.5) satisfies \( w \in W^{t,p}(\Gamma) \) for some value of \( p \in (p_0,2] \), where \( 3/2 < p_0 < 2 \) depends on the angles at the corners of \( \Gamma \). For technical reasons, we assume \( p > 3/2 \) here (recall (5.3)). Note that \( \sigma = C \nabla w \in W^{t-2,p}(\Gamma;S) \).

#### 6.1 Estimate the PDE Error

First, we derive an error estimate that ignores the geometric error, i.e. the continuous and discrete problems are posed on the exact domain.

**Theorem 6.1** Adopt Hypothesis 1 and note that \( \sigma = C \nabla w \) and \( w \in \mathcal{W} \) also satisfy (3.10) on the true domain \( \Gamma \). Furthermore, let \( r \geq 0 \) be the degree of \( V_h \), and let \( \sigma_h \in V_h, w_h \in W_h \) be the discrete solution of (5.13) on \( \Gamma \). Then, we obtain

\[
\begin{align*}
\| \sigma - \sigma_h \|_{0,h} + \| \nabla I(w-w_h) \|_{L^2(\Gamma)} & \lesssim Ch^{\min(r+2,t-1)-2/p}, \\
\text{when } r \geq 1: \quad \| w - w_h \|_{2,h} & \lesssim Ch^{\min(r+1,t-1)-2/p} \quad \text{(6.1)}
\end{align*}
\]

where \( C > 0 \) depends on \( f \), the domain \( \Gamma \), and the shape regularity of the mesh.

**Proof.** With coercivity and the inf-sup condition in hand, the proof is a standard application of error estimates for mixed methods, so we omit the details. See (Arnold & Walker, 2020, Supp. Mat.) for a proof in the case of flat domains. \( \square \) The above result generalizes (Blum & Rannacher, 1990, Thm. 5.1) to surfaces.
6.2 Estimate the Geometric Error

Next, we approximate the domain using curved surface elements.

**Lemma 6.1** Recall the map \( \Psi^m : \Gamma^m \to \Gamma \), with \( \Psi^m |_T := \Psi^m |_T \), from Section 4.1, adopt (5.17), and the hypothesis of 6.1. Let \( \tilde{\sigma}_h \in V_h^m \), \( \tilde{w}_h \in W_h^m \) be the discrete solution of (5.13), with \( f \) replaced by \( \tilde{f} := f \circ \Psi^m \mu_h \), where \( \mu_h \) is the change in area when mapping from \( \Gamma \) to \( \Gamma^m \). Take \((\tilde{\sigma}_h, \tilde{w}_h)\) from Theorem 6.1, and let \( \tilde{\sigma}_h \in V_h^m \), \( \tilde{w}_h \in W_h^m \) be the mapped discrete solutions onto \( \Gamma^m \) using (4.11). In other words, \( \tilde{\sigma}_h \circ \Psi^m \) and \( \tilde{\sigma}_h \) are related through the matrix Piola transform (recall Remark 4.1), and \( \tilde{w}_h = \Psi^m \circ \tilde{w}_h \), element-wise. Similarly, we map the test functions \( \tilde{\phi}_h \in V_h \), \( \tilde{v}_h \in W_h \) to \( \tilde{\phi}_h \in V_h^m \), \( \tilde{v}_h \in W_h^m \).

Then, we obtain the error equations for the geometric error:

\[
d^m (\tilde{\sigma}_h - \tilde{\sigma}_h, \tilde{\phi}_h) + b_m^m (\tilde{\phi}_h, \tilde{w}_h - \tilde{\varphi}_h) + b_m^m (\tilde{\sigma}_h - \tilde{\sigma}_h, \tilde{v}_h) = E_0 (\tilde{\phi}_h, \tilde{v}_h),
\]

for all \((\tilde{\phi}_h, \tilde{v}_h) \in W_h^m \times V_h^m \), where

\[
|E_0 (\tilde{\phi}_h, \tilde{v}_h)| \leq C h^q (\|\tilde{\phi}_h\|_{0, h,m} + \|\tilde{v}_h\|_{2, h,m}) \|f\|_{H^{-1} (\Gamma)},
\]

where \( q = m \) when \( m = r + 1 \), otherwise \( q = m - 1 \).

**Proof.** We will need \( \tilde{\sigma}_h, \tilde{\phi}_h \in V_h^1 \), \( \tilde{w}_h, \tilde{v}_h \in W_h^1 \) as in Theorem 4.8; recall the notation from Theorem 4.1. Applying (4.17) with \( m, l \) replaced by \( \infty, m \), respectively, we get

\[
b_h (\tilde{\phi}_h, \tilde{v}_h) = b_h^m (\tilde{\phi}_h, \tilde{v}_h) + O (h^m) \|\tilde{\phi}_h\|_{0, h,m} \left( \|\tilde{v}_h\|_{2, h,m} + \|\tilde{w}_h\|_{H^1 (\Gamma^m)} \right) - b_h (\tilde{\phi}_h, (F - F^m) \cdot P_0 V_T \tilde{v}_h),
\]

where we note the boundary conditions (either \( \tilde{\varphi}_h \) or \( \tilde{\phi}_h^m \) vanishes on \( \partial \Gamma \)). Recalling (5.17), i.e. \( F^m := \mathcal{J}^m F \), if \( m = r + 1 \), the Fortin property (5.8) yields \( b_h^m (\tilde{\phi}_h, (F - F^m) \cdot P_0 V_T \tilde{v}_h) = 0 \). If \( m \neq r + 1 \), then a straightforward estimate shows \( b_h^m (\tilde{\phi}_h, (F - F^m) \cdot P_0 V_T \tilde{v}_h) \leq C h^{m-1} \|\tilde{\phi}_h\|_{0, h,m} \|\tilde{v}_h\|_{2, h,m} \), where we used equivalence of norms (4.9), (4.15).

Therefore, using (4.16) and (4.32), the first line in (5.13) (with \( m = \infty \)) maps to

\[
d^m (\tilde{\sigma}_h, \tilde{\phi}_h) + b_m^m (\tilde{\phi}_h, \tilde{w}_h) = I_1, \forall \tilde{\phi}_h \in V_h^m,
\]

where \( 1 \leq m \leq k \) and \( C > 0 \) is a constant depending only on \( \Gamma \) such that

\[
|I_1| \leq C h^q \|\tilde{\phi}_h\|_{L^2 (\Gamma^m)} \left( \|\tilde{\sigma}_h\|_{L^2 (\Gamma^m)} + \|\tilde{w}_h\|_{2, h,m} \right),
\]

where \( q \) was defined earlier. The second equation in (5.13) (with \( m = \infty \)) maps to

\[
b_m^m (\tilde{\sigma}_h, \tilde{v}_h) = - \langle f \circ \Psi^m \mu_h, \tilde{v}_h \rangle_{\Gamma^m} + I_2, \forall \tilde{v}_h \in W_h^m,
\]

where, for some constant \( C > 0 \) depending only on \( \Gamma \),

\[
|I_2| \leq C h^q \|\tilde{\sigma}_h\|_{L^2 (\Gamma^m)} \|\tilde{v}_h\|_{2, h,m}.
\]

Then, subtracting (5.13) (with \( 1 \leq m \leq k \)) for the solution \((\tilde{\sigma}_h, \tilde{w}_h)\) from the above equations, combining everything, noting the a priori estimate (5.14), and the fact that \( \|f\|_{H^{-1} (\Gamma^m)} \leq C \|f\|_{H^{-1} (\Gamma)} \), gives (6.2), (6.3).
THEOREM 6.2 Adopt the hypothesis of Lemma 6.1. Then, the following error estimate holds
\[ \| \sigma_h - \hat{\sigma}_h \|_{0,h,m} + \| \hat{\sigma}_h - \hat{\sigma}_h \|_{2,h,m} \leq Ch^q \| f \|_{H^{-1}(\Gamma)}, \] (6.9)
for some uniform constant \( C > 0 \).

Proof. From (6.2), choose \( \hat{v}_h \) = 0 and use Lemma 5.3 to get
\[ \beta_h \| \hat{\sigma}_h - \hat{\sigma}_h \|_{2,h,m} \leq \sup_{\tilde{\sigma}_h \in V^m_h} \frac{|h^m(\phi_h, \hat{\sigma}_h - \hat{\sigma}_h)|}{\| \phi_h \|_{0,h,m}} \leq \sup_{\tilde{\sigma}_h \in V^m_h} \frac{|h^m(\sigma_h - \sigma_h, \phi_h)|}{\| \phi_h \|_{0,h,m}} + |E_0(\hat{\phi}_h, 0)| \] (6.10)
where we used the norm equivalence (4.15). Next, choose \( \hat{\phi}_h = \sigma_h - \hat{\sigma}_h \) and \( \hat{v}_h = -(\hat{\sigma}_h - \hat{\sigma}_h) \) in (6.2) to get
\[ \alpha_0 \| \hat{\sigma}_h - \hat{\sigma}_h \|_{L^2(\Gamma)} \leq Ch^q \left( \| \hat{\sigma}_h - \hat{\sigma}_h \|_{0,h,m} + \| \hat{\sigma}_h - \hat{\sigma}_h \|_{2,h,m} \right) \| f \|_{H^{-1}(\Gamma)} \]
\[ \leq Ch^q \left( \| \hat{\sigma}_h - \hat{\sigma}_h \|_{0,h,m} + Ch^q \| f \|_{H^{-1}(\Gamma)} \right) \| f \|_{H^{-1}(\Gamma)} \] \[ \leq C(h^q)^2 \| f \|_{H^{-1}(\Gamma)}^2 + Ch^q \| \hat{\sigma}_h - \hat{\sigma}_h \|_{L^2(\Gamma)}^2 \| f \|_{H^{-1}(\Gamma)} \]
where we used (6.10), norm equivalence (5.5), and a weighted Cauchy inequality. Then, by combining the above results, we get the assertion. \( \square \)

6.3 Estimate the Total Error
We will combine Theorem 6.1 and Theorem 6.2 to get the total error.

THEOREM 6.3 (general error estimate) Adopt the hypotheses of Theorem 6.1, Lemma 6.1. If \( m \geq r + 1 \), then
\[ \| \sigma - \hat{\sigma}_h \circ (\Psi^m)^{-1} \|_{0,h} + \| \nabla_{\Gamma}(w - \hat{\sigma}_h \circ (\Psi^m)^{-1}) \|_{L^2(\Gamma)} \leq Ch^{\min(r+2j-1)-2/p}, \]
\( r \geq 1 : \) \[ \| w - \hat{\sigma}_h \circ (\Psi^m)^{-1} \|_{2,h} \leq Ch^{\min(r+2j-1)-2/p}, \] (6.12)
\( r = 0 : \) \[ \| \nabla_{\Gamma}(w - \hat{\sigma}_h \circ (\Psi^m)^{-1}) \|_{L^2(\Gamma)} \leq Ch, \]
where \( C > 0 \) depends on \( f \), the domain \( \Gamma \), and the shape regularity of the mesh.

Proof. By the triangle inequality and using the properties of the map \( \Psi^m \), we have
\[ \| \sigma - \hat{\sigma}_h \circ (\Psi^m)^{-1} \|_{0,h} \leq \| \sigma - \hat{\sigma}_h \circ (\Psi^m)^{-1} \|_{0,h} + \| \hat{\sigma}_h \circ (\Psi^m)^{-1} - \hat{\sigma}_h \circ (\Psi^m)^{-1} \|_{0,h} \]
\[ \leq \| \sigma - \sigma_h \|_{0,h} + \| \sigma_h - \hat{\sigma}_h \circ (\Psi^m)^{-1} \|_{0,h} + C \| \hat{\sigma}_h - \hat{\sigma}_h \|_{0,h,m}. \] (6.13)
Focusing on the middle term, the Piola transform in (4.12) yields
\[ \| \sigma_h - \hat{\sigma}_h \circ (\Psi^m)^{-1} \|_{0,h} \leq C \| \sigma_h \circ F - \hat{\sigma}_h \circ F \|_{0,h,1} \leq Ch^{r+1} \| \sigma_h \|_{0,h,m} \leq Ch^{r+1} \| f \|_{H^{-1}(\Gamma)}, \] (6.14)
where we use the approximation properties in (4.3). Whence,

$$\|\sigma - \hat{\sigma}_h \circ (\Psi^m)^{-1}\|_{0,h} \leq C \max \left( h^{r+1}, h^{\min(r+2, r-1)-2/p} \right),$$  \hspace{1cm} (6.15)

where $C > 0$ depends on $f$. Taking a similar approach for the other terms involving $w - \hat{w}_h \circ (\Psi^m)^{-1}$ delivers the estimates.

**Corollary 6.1** Adopt the hypothesis of Theorem 6.3, but assume $\Gamma, \Sigma$ are smooth, and the data and solution $(\sigma, w)$ are smooth. If $r > 0$ is the degree of $V_h,$ then

$$\|\sigma - \hat{\sigma}_h \circ (\Psi^m)^{-1}\|_{0,h} + \| \nabla \Gamma (w - \hat{w}_h \circ (\Psi^m)^{-1})\|_{L^2(\Gamma)} + h \| w - \hat{w}_h \circ (\Psi^m)^{-1}\|_{2,h} \leq Ch^{r+1},$$  \hspace{1cm} (6.16)

where $C > 0$ depends on $w$, the domain $\Gamma$, and the shape regularity of the mesh.

**Remark 6.1** From Theorem 6.2, if $m < r + 1$, the error is sub-optimal, i.e., is $O(h^{m-1})$ for a smooth solution. However, the numerical experiments in Section 7 have better rates. When $m < r + 1$, the worst case error for $\hat{\sigma}_h$ is $O(h^{m-1/2})$ and for $\hat{w}_h$ (in $H^1$) is $O(h^m)$.

### 6.4 Inhomogeneous Boundary Conditions

We now explain how to extend the above theory to handle non-vanishing boundary conditions. First, construct a function $g \in W^{l,p}(\Gamma)$, such that the displacement satisfies $w = g$ on $\Sigma_\Gamma \cup \Sigma_\Gamma$, $\partial_n w = \partial_n g$ on $\Sigma_\Gamma$, and $\Sigma (w - g) = 0$. Next, construct a function $p \in W^{l-2,p}(\Gamma; S)$, such that the normal-conormal moment satisfies $n^i \sigma_n = n^i \rho n$ on $\Sigma_\Gamma \cup \Sigma_\Gamma$, where $l \geq 3$, $3/2 < p \leq 2$ (recall Hypothesis 1). In addition, let $\zeta \in W^{l-3,p}(\Sigma_\Gamma)$ and $\zeta_p \in \mathbb{R}$, for all $p \in Y_{\Sigma_\Gamma}$ (recall (3.1)) such that

$$-n \cdot (\nabla \Gamma \sigma) - t \cdot \nabla \Gamma (n^i \sigma t) = \zeta, \text{ on } \Sigma_\Gamma,$$

$$-n \cdot \sigma t = \zeta_p, \text{ for all } p \in Y_{\Sigma_\Gamma}. \hspace{1cm} (6.17)$$

Then (3.10) is replaced by the problem of determining $(\sigma, w) = (\hat{\sigma} + \rho, \hat{w} + g)$, with $\hat{\sigma} \in Y_\Gamma$, $\hat{w} \in W_\Gamma$ (i.e., with homogeneous boundary conditions) such that

$$a(\hat{\sigma}, \varphi) + b_h(\varphi, \hat{w}) = -a(\rho, \varphi) - b_h(\varphi, g) + (\varphi^m, n \cdot \nabla \Gamma \varphi)_{\Sigma_\Gamma}, \forall \varphi \in Y_\Gamma,$$

$$b_h(\hat{\sigma}, \varphi) = - (f, \varphi)_{\Gamma} - b_h(\rho, \varphi) - (\zeta, \varphi)_{\Sigma_\Gamma} - \sum_{p \in Y_{\Sigma_\Gamma}} \zeta_p v_h(p), \forall \varphi \in Y_\Gamma. \hspace{1cm} (6.18)$$

Note that the right-hand-side in the first equation of (6.18) simplifies to $-a(\rho, \varphi) - b_h(\varphi, g)$, where $b_h(\varphi, v) := b_h(\varphi, v) - (\varphi^m, n \cdot \nabla \Gamma v)_{\Sigma_\Gamma}$ (i.e., it has no boundary term).

Similarly, the corresponding (intermediate) discrete problem (5.13), on the exact domain, is replaced by finding $(\sigma_h, w_h) = (\hat{\sigma}_h + \rho_h, \hat{w}_h + g_h)$, with $\hat{\sigma}_h \in V_h$, $\hat{w}_h \in W_h$ such that

$$a(\hat{\sigma}_h, \varphi) + b_h(\varphi, \hat{w}_h) = -a(\rho_h, \varphi) - b_h(\varphi, g_h) - (\varphi^m_h, n \cdot \nabla \Gamma \varphi)_{\Sigma_\Gamma}, \forall \varphi \in V_h,$$

$$b_h(\hat{\sigma}_h, \varphi) = - (f, \varphi)_{\Gamma} - b_h(\rho_h, \varphi) - (\zeta, \varphi)_{\Sigma_\Gamma} - \sum_{p \in Y_{\Sigma_\Gamma}} \zeta_p v_h(p), \forall \varphi \in W_h. \hspace{1cm} (6.19)$$

where $\rho_h = P_h \rho$, and $P_h : H^1_0(\Gamma) \to V_h$ is the $L^2(\Gamma)$ projection, i.e., $\rho_h$ satisfies

$$(\rho_h - \rho, \varphi)_{\Sigma_\Gamma} + (n^T [\rho_h - \rho] n, \varphi^m_h)_{\Sigma_\Gamma} = 0, \text{ for all } \varphi \in V_h. \hspace{1cm} (6.20)$$
and \( g_h = \mathcal{J}_h g \). An error estimate between the solutions of (6.18) and (6.19), analogous to Theorem 6.1, follows similarly with the following additional steps. First, estimate \( b_h (\rho - \rho_h, v_h) \leq \| \rho - \rho_h \|_{0, h} v_h \|_{2, h} \), note \( \| \rho - \rho_h \|_{0, h} \leq \| \rho - \Pi^h \rho \|_{0, h} \) and use the approximation properties of \( \Pi^h \) Brezzi & Raviart (1976); Brezzi et al. (1980); Arnold & Walker (2020). Next, estimate \( \hat{b}_h (\Phi_h, g - g_h) \) and \( (\hat{\Phi}_h, n \cdot \nabla \Gamma (g - g_h))_\Sigma \) with (5.9).

Finally, the discrete problem on the discrete domain is to find \((\hat{\sigma}_h, \hat{v}_h) = (\hat{\sigma}_h + \hat{\rho}_h, \hat{v}_h + \hat{g}_h)\), with \( \hat{\sigma}_h \in V_h^m \), \( \hat{v}_h \in W_h^m \) such that

\[
\begin{align}
\alpha^m (\hat{\sigma}_h, \Phi_h) + b_h^m (\Phi_h, \hat{v}_h) &= -\alpha^m (\hat{\rho}_h, \Phi_h) - \hat{b}_h^m (\Phi_h, \hat{g}_h) \\
&\quad - (\hat{\Phi}_h^m, \hat{n} \cdot [\nabla \Gamma (\hat{g}_h - \hat{\xi}_h)]_\Sigma^m, \Phi_h)_{V_h^m}, \\
b_h^m (\hat{\sigma}_h, \hat{v}_h) &= - (\hat{f}, \hat{v}_h)_\Gamma^m - b_h^m (\hat{\rho}_h, \hat{v}_h) \\
&\quad - (\hat{\xi}_h, \hat{v}_h)_\Sigma^m - \sum_{p \in Y_h} \hat{\xi}_p \hat{v}_h (p), \forall \hat{v}_h \in W_h^m,
\end{align}
\]

(6.21)

where \( \hat{\rho}_h := P_h^m \hat{\rho} \), with \( \hat{\rho} \) given by \( \rho \circ \Psi^m = \text{Piola}(\hat{\rho}) (\hat{x}) \) (recall (4.12)), and \( P_h^m : H^0_0 (\Gamma^m) \rightarrow V_h^m \) is the \( L^2 (\Gamma^m) \) projection on \( \Gamma^m \), \( \hat{g}_h := \mathcal{J}_h \hat{g} \), with \( \hat{g} := g \circ \Psi^m \), \( \hat{\xi}_h := (\nabla \Gamma g) \circ \Psi^m \), and \( \hat{\xi}_h := \hat{g}_h \circ \Psi^m \). To obtain an analogous result to Theorem 6.3, we need to generalize Lemma 6.1, i.e. we need to show that

\[
\alpha^m (\hat{\sigma}_h - \hat{\sigma}_h, \Phi_h) + b_h^m (\Phi_h, \hat{v}_h - \hat{\hat{v}}_h) + b_h^m (\hat{\sigma}_h - \hat{\sigma}_h, \hat{v}_h) = E_1 (\Phi_h, \hat{v}_h),
\]

for all \( \Phi_h \in V_h^m \) and \( \hat{v}_h \in W_h^m \), where

\[
|E_1 (\Phi_h, \hat{v}_h)| \leq C h^s (\| \Phi_h \|_{0, h} + \| v_h \|_{2, h}) \cdot \\
\cdot (\| \rho \|_{W^{s, 2} (\Gamma^m)} + \| g \|_{W^{s, 2} (\Gamma^m)} + \| \hat{\xi}_h \|_{L^2 (\Sigma^m)} + \| \hat{\sigma}_h \|_{0, h} + \| \hat{w}_h \|_{2, h}),
\]

(6.23)

where \( s \) is the exponent appearing in (6.12). This also follows the same outline, but we note the following. (1) Estimating \( \hat{b}_h^m (\hat{\Phi}_h, \hat{g}_h - \hat{\xi}_h) \) with (4.17) is simpler because the last boundary term in (4.17) does not appear; then use Lemma 5.1; (2) noting that \( \hat{g}_h = g_h \circ \Psi^m \), \( (\Phi_h^m, \hat{n} \cdot \nabla \Gamma (g_h - g))_\Sigma \) is mapped to \( (\Phi_h^m, \hat{n} \cdot \nabla \Gamma (\hat{g}_h - \hat{\xi}_h))_\Sigma \) (plus residual terms) and is compared against \( (\Phi_h^m, \hat{n} \cdot [\nabla \Gamma (\hat{g}_h - \hat{\xi}_h)]_\Sigma) \); (3) finally, estimate \( (\Phi_h^m, \hat{n} \cdot [\nabla \Gamma (\hat{g}_h - \hat{\xi}_h)]_\Sigma) \) using similar arguments as in the proof of Theorem 4.8. With this, generalizing Theorems 6.2 and 6.3, and Corollary 6.1, is immediate and we obtain the following.

**Theorem 6.4** (inhomogeneous boundary conditions) Adopt the hypotheses of Theorem 6.3, except assume that \( (\Phi, w) \) satisfies (6.18) and \( (\hat{\Phi}_h, \hat{w}_h) \) solves (6.21). If \( m \geq r + 1 \), then \( (\Phi, w) \) and \( (\hat{\Phi}_h, \hat{w}_h) \) satisfy the same estimates as in (6.12). In addition, if \( \Gamma \) and \( \Sigma \) are smooth, and the data and solution \( (\Phi, w) \) are smooth, then if \( r \geq 0 \) is the degree of \( V_h \), then \( (\Phi, w) \) and \( (\hat{\Phi}_h, \hat{w}_h) \) satisfy the same estimates as in (6.16).

**7. Numerical Results**

We present numerical results for several different domains, both with and without boundary. The discrete domains were generated by either interpolating charts on a sequence of uniformly refined grids, or
by creating an initial piecewise linear triangulation of the implicit, closed surface (using Walker (2013)) and interpolating the closest point map. As above, the finite element spaces $V_h$ and $W_h$ are of degree $r$ and $r + 1$ respectively, where $r \geq 0$, and the geometric approximation degree is denoted $m$. All computations were done with the Matlab/C++ finite element toolbox FELICITY Walker (2018), where we used the “backslash” command in Matlab to solve the linear systems.

From (5.17), recall that $F^m := \mathcal{F}^1_h m \Psi^1$, which is possible to implement, but inconvenient. Instead, we first compute $F^{m+1}$ by standard nodal interpolation, then we define $F^m := \mathcal{F}^1_h m F^{m+1}$, which is easy to implement to the piecewise linear triangulation of $\Gamma^1$. Moreover, the accuracy is not affected.

As for the boundary data, $\hat{\xi}_h$, $\xi$, and $\hat{\rho}_h$ only need to be computed on the boundary $\Sigma^m$; in fact, only the boundary part of the $L^2$ projection $P^m_h$ needs to be computed. For the free conditions, $\hat{\xi}_f$ is implemented exactly since a corner coincides with a fixed vertex in the mesh. The other free condition $\hat{\xi}_f$ can be computed exactly at any point on $\Sigma_f$ using the manufactured solution, so that $\hat{\xi}_f^{m+1, m+1}$ on $\Sigma^m_f$, where $\mathcal{F}^m_h$ is the standard nodal interpolation onto degree $m+1$ polynomials, is well-defined because $\Sigma^m_f$ interpolates $\Sigma_f$. Then, we define $\hat{\xi}_f := \hat{\sigma}_h \left( \mathcal{F}^{m+1, m+1} \hat{\xi}_f \right) \circ \Phi^{m+1}$ on $\Sigma^m_f$, where $\hat{\sigma}_h$ denotes the (local) change in length between $\Sigma^m_f$ and $\Sigma^m_f$. For convenience, we compute $\hat{\sigma}_h = \| w - \hat{w}_h \|_{L^2(\Gamma^f)}$, $\| \nabla_F (w - \hat{w}_h) \|_{L^2(\Gamma^f)}$, $\| w - \hat{w}_h \|_{2, h, m}$, $\| \sigma - \hat{\sigma}_h \|_{0, h, m}$, where the exact solution has been extended by analytic continuation. These errors can be related to the ones in (6.16) by basic arguments and a triangle inequality; a similar approach was used in (Arnold & Walker, 2020, Sec. 6.1). The estimated order of convergence (EoC) is computed by using the ratio of the error between two successive uniform refinements for the final mesh size.

7.1 Saddle Surface

7.1.1 Square. The domain is given by $(U, \chi)$, where $U = [0, 1] \times [0, 1]$ and $\chi(u_1, u_2) = (u_1, u_2, \cos(2\pi(u_2 - 0.5)) - \cos(2\pi(u_1 - 0.5)))$. The exact solution, on the reference domain, is

$$w \circ \chi(u_1, u_2) = \sin(6.5u_1) \cos(5.9u_2).$$

(7.1)

Table 1 shows the estimated orders of convergence (EoC) for the case of simply-supported boundary conditions; the clamped case gave similar numbers and free boundary conditions had slightly better rates. The optimal orders of convergence, based on the degree of the elements, is $r + 1$ for the three quantities $|\hat{w}_h|_{H^1}$, $|\hat{\sigma}_h|_{0, h}$, and $r$ for $|\hat{w}_h|_{2, h}$. The convergence is a bit better than expected. For example, when $m = 1$ and $r = 1, 2$, the convergence rate for $|\hat{\sigma}_h|_{0, h}$ is reduced, but not as much as our analysis suggests (see Remark 6.1). Similarly, when $m = 2$ and $r = 3$, the EoC for $|\hat{\sigma}_h|_{0, h}$ is reduced. However, $\hat{w}_h$ is not so adversely affected.

7.1.2 Three-Leaf Domain. The domain is given by $(U, \chi)$, where the boundary of $U$ is parametrized by

$$x(t) = [1 + 0.4 \cos(3t)] \cos(t), \quad y(t) = [1 + (0.4 + 0.22 \sin(t)) \cos(3t)] \sin(t),$$

(7.2)

for $0 \leq t \leq 2\pi$; this choice of domain avoids any spurious symmetries (e.g. the unit disk; see (Arnold & Walker, 2020, Sec. 6.2)). The surface parametrization is given by $\chi(u_1, u_2) = (u_1, u_2, (u_2 - 0.5)^2 - (u_1 - 0.5)^3)$. The exact solution, on the reference domain, is

$$w \circ \chi(u_1, u_2) = \sin(2\pi u_1) \cos(2\pi u_2).$$

(7.3)
Table 1. EoC for the saddle square with simply-supported boundary conditions. \(N_T\) is the number of triangles in the final mesh after multiple uniform refinements. Italics indicate the case \(m = r + 1\), which is the optimal case proven in this paper.

The curved element mapping is composed from two maps (recall (5.17)). The first map is a Lenoir type map Lenoir (1986) described in Arnold & Walker (2020) that creates a curved triangulation that optimally approximates \(U\); the second map is the parametrization \(\chi\). We then apply (5.17) to the composed map.

Table 2 shows the estimated orders of convergence (EoC) for the case of simply-supported boundary conditions; the clamped case gave similar numbers and free boundary conditions had slightly better rates. The optimal orders of convergence, based on the degree of the elements, is \(r + 1\) for the three quantities \(\|\hat{w}_h\|_{H^1}\), \(\|\hat{\sigma}_h\|_{0,h}\), and \(r\) for \(\|\hat{w}_h\|_2\). The convergence is a bit better than expected. For example, whenever \(m < r + 1\), the convergence rate for \(\|\hat{\sigma}_h\|_{0,h}\) is roughly \(O(h^{m-1/2})\), which is not as bad as our analysis suggests (see Remark 6.1). However, \(\hat{w}_h\) is not so adversely affected.

Table 2. EoC for the saddle three-leaf domain with simply-supported boundary conditions. \(N_T\) is the number of triangles in the final mesh after multiple uniform refinements. Italics indicate the case \(m = r + 1\), which is the optimal case proven in this paper.

7.2 Spherical Cap

The domain is given by \((U, \chi)\), where \(U\) is the unit disk, centered at the origin, and \(\chi(u_1, u_2) = \)
\((u_1, u_2, [(1.5)^2 - (u_1^2 + u_2^2)]^{1/2} - [(1.5)^2 - 1]^{1/2})\). The exact solution, on the reference domain, is
\[
w \circ \chi(u_1, u_2) = \sin(6.7u_1) \cos(6.1u_2).
\]
\[(7.4)\]

The curved element mapping is composed from two maps analogous to Section 7.1.2. The numerical solution \(\hat{w}_h\) is shown in Figure 4 for the case of simply-supported boundary conditions; Table 3 shows the corresponding estimated orders of convergence (EoC). The clamped case gave similar rates and free boundary conditions had better rates. The format is similar to Section 7.1. The convergence is again better than expected. For example, when \(m = 1\) and \(r = 1, 2\), the convergence rate for \(\|\hat{\sigma}_h\|_{0,h}\) is reduced, but not as much as our analysis suggests (see Remark 6.1). For the other cases, there is no reduction below the rate given by \(m\); e.g. the rate for \(\|\hat{w}_h\|_{2,h}\) is always at least \(O(h^{m-1})\). In addition, \(\hat{w}_h\) is not so adversely affected.

Table 3. EoC for the spherical cap with simply-supported boundary conditions. \(N_T\) is the number of triangles in the final mesh after multiple uniform refinements. Italics indicate the case \(m = r + 1\), which is the optimal case proven in this paper.

When uniformly free boundary conditions are used on the spherical cap domain, the null-space \(\mathcal{Z}(\Gamma)\) of the covariant Hessian contains three linearly independent functions \(\{z_i\}^3_{i=1}\): the constant function \(z_1\) and two of the isometric rotations of the sphere, \(z_2, z_3\), which are illustrated in Figure 5. Note that the other rotation (not present) cannot be represented as the gradient of a function. Eigenvalues of the discrete finite element system were computed with Matlab and are shown in Table 4, where \(\{\lambda_i\}^3_{i=1}\) are the corresponding eigenvalues of \(\{z_i\}^3_{i=1}\). The first three eigenvalues of the continuous problem are...
zero, but for the numerical approximation, only \( \lambda_1 \) is machine precision; \( \lambda_2, \lambda_3 \) are not zero but are much smaller than the other eigenvalues and appear to converge to zero (c.f. (Reusken, 2018, Sec. 6)).

Table 4. Eigenvalues for the spherical cap with free boundary conditions for \( m = 3 \) and \( r = 2 \) (the results were similar for other choices of \( m = 3 \) and \( r = 2 \)). Level refers to the refinement level. The eigenvalue \( \lambda_1 \) (not shown) is machine precision \( \approx 10^{-14} \).

Note that \( \lambda_2, \lambda_3 \) are not zero, but are much smaller than the other eigenvalues listed.

7.3 Torus

The domain is a torus described by the zero level set of the function: \( b(x,y,z) = (x^2 + y^2 - (6/10))^2 + (3/2)z^2 - (1/4) \). The exact solution, extended everywhere, is

\[
\hat{w}(x,y,z) = \sin(1.1x) + \cos(1.2y) + \sin(1.3z). \tag{7.5}
\]

The “parametrization” is built from the closest point map. Table 5 shows the estimated orders of convergence (EoC). The convergence is better than expected. For instance, the convergence rate for \( \|\hat{w}_h - \hat{w}\|_{H^1} \) and \( \|\hat{\sigma}_h\|_{0,h} \) is \( O(h^{\min(m,r+1)}) \).

---

Fig. 5. Killing fields on a spherical cap. Top shows \( z_2 \) (in color) with gradient (Killing) field \( \nabla z_2 \) as black arrows. Bottom shows \( z_3 \).
such that $w \in \mathcal{G}$

The domain is a genus-5 surface described by the zero level set of the function: $b(x, y, z) = (x^4 + y^4 + z^4) - (x^2 + y^2 + z^2) + 0.4$ (see Figure 6). We solve the biharmonic problem $\Delta^2 w = f$ on $\Gamma$ by modifying the method in the following way. In terms of index notation, one can show that $z$ by standard mixed finite element theory Boffi (2013). In fact, if $\kappa$ is the Gauss curvature of the manifold Berger (2003); do Carmo (1992); Petersen (2006). Therefore, solving the biharmonic problem: find $w \in \mathcal{W}(\Gamma)$ such that $\int_\Gamma (\nabla^a \nabla^b w) \nabla^c w \alpha \kappa dS(g) = \int_\Gamma (\nabla^a \nabla^b w) \nabla^c w \alpha \kappa dS(g) - \int_\Gamma \kappa \alpha \nabla^c w \alpha \kappa dS(g)$, where $\kappa$ is the Gauss curvature of the manifold $\kappa$ (see Kellogg & Liu (1996)). However, for general surfaces, convergence is not obvious and is a point of future work.

Table 5. EoC for the torus; same format as earlier EoC tables.

### 7.4 Biharmonic on a Genus-5 Surface

The discrete mixed method for (7.6) is the following modification of (5.13): find $\sigma_h \in V^m_h$, $w_h \in W^m_h$ such that

$$a^m(\sigma_h, \phi) + b^m(\phi, w_h) = 0, \forall \phi \in V^m_h,$$

$$b^m(\sigma_h, v) = c^m(w_h, v), \forall v \in W^m_h,$$

(7.7)

where $c^m(w, v) := \int_\mathcal{G} \kappa \nabla_r w \cdot \nabla_r z$. When $\kappa \geq 0$, the convergence of this scheme can be established by standard mixed finite element theory Boffi et al. (2013). In fact, if $c^m(\cdot, \cdot)$ is only weakly coercive ($\kappa$ slightly negative), then one can still show convergence; see Kellogg & Liu (1996). However, for general surfaces, convergence is not obvious and is a point of future work.

We now present a numerical example illustrating that convergence seems to hold even for very general surfaces. The exact solution, extended everywhere, is given by (see Figure 6)

$$w(x, y, z) = \cos(0.9x) + \sin(1.1y) + \cos(1.3z).$$

Table 6 shows the estimated orders of convergence (EoC). The convergence is better than expected; the convergence rate for $|\hat{w}_h|_{H^1}$ and $||\hat{G}_h||_{0,0}$ is at least $O(h^{min(m,r+1)})$. 

$$\int_\Gamma \nabla \Delta w \cdot \nabla = \int_\Gamma \kappa \nabla \Delta w \cdot \nabla z = \langle f, z \rangle_{\Gamma}, \forall z \in \mathcal{W}(\Gamma).$$

8. Conclusion

We have demonstrated that the classic HHJ method for the Kirchhoff plate equation extends to general embedded surfaces in $\mathbb{R}^3$ either closed or with boundary that have a combination of clamped, simply-supported, and free conditions imposed. Moreover, optimal convergence is guaranteed so long as $m \geq r + 1$, where $m$ is the degree of surface approximation and $r + 1$ is the degree of the Lagrange displacement variable. If $m < r + 1$, some degradation in convergence occurs. The numerical experiment in Section 7.1.2 gave the best test of the method, but the convergence was still better than our estimates suggest when $m < r + 1$. All other examples had slightly better rates. When $m < r + 1$, the error estimates could be improved in the case of closed surfaces characterized by a signed distance function. Indeed, the closest point map enjoys nice approximation properties. But for surfaces with boundary, the parametric approach is more convenient, though multiple charts may be required.

It is worth noting that the classic Ciarlet-Raviart method for solving the biharmonic problem on flat domains is not appropriate when non-clamped boundary conditions are used, and the same holds for surfaces. This is connected to the classic Babuška paradox Babuška & Pitkäranta (1990) which
concerns polygonal approximation of the domain. However, as was shown in Arnold & Walker (2020) for flat domains, the lowest order surface HHJ method converges optimally with only piecewise linear approximation of the domain, despite the fact that curvature of the boundary is important for accurately capturing boundary conditions (e.g. simply-supported conditions). This is a manifestation of the geometrically non-conforming aspect of the HHJ method, originally noted in Arnold & Walker (2020).

Adapting the surface HHJ method to solve the surface biharmonic problem on closed surfaces requires an extra (lower order) term in the formulation involving the Gauss curvature (see Section 7.4). The theory here extends readily to surfaces of positive, or slightly negative, Gauss curvature. For general surfaces, it is not obvious, however the method appears to perform optimally.

A.1 Intrinsic Differential Geometry

We review the differential geometry tools needed for working on manifolds Kreyszig (1991); do Carmo (1992, 1976); Ciarlet (2013); Hebey (1996). Specifically, we review the basic notation of covariant, contravariant, and other differential geometry concepts.

Consider a d-dimensional Riemannian manifold \((\Gamma, g_{ab})\), where \(g_{ab}\) is the given metric tensor (discussed below) defined over a (reference) domain \(U \subset \mathbb{R}^d\). A point in \(U\) is denoted by \((u^1, u^2, \ldots, u^d)\); in the special case of \(d = 2\) that we are mainly concerned with, we may use \((u, v) \in U\). We refer to variables defined on \(U\) as intrinsic quantities.

Tensor Index Notation. We use lower-case Greek indices \((\alpha, \beta, \gamma, \text{ etc.})\), which take values in \(\{1, 2, \ldots, d\}\) when referring to intrinsic variables. For example, \(\partial_\alpha\) is the partial derivative with respect to the coordinate \(u^\alpha\) for \(\alpha \in \{1, 2, \ldots, d\}\). Covariant vectors are denoted with lower indices, e.g. \((v_1, v_2, \ldots, v_d)\) and contravariant vectors are denoted with upper indices, e.g. \((v^1, v^2, \ldots, v^d)\). The \(\beta\)-th component of a covariant (contravariant) derivative is denoted by \(\nabla_\beta \equiv \nabla^{\beta}\). Similar considerations hold for tensors.

Furthermore, we use the letters \(a\)-\(h\) (with a different font for emphasis) as a non-numerical label to indicate a covariant, contravariant, or mixed tensor. For example, \(v_a\) refers to a covariant vector (not just a single component), i.e. \(v_a \equiv (v_1, \ldots, v_d)\). When convenient, we use bold-face for vector and tensor quantities instead of writing out indices.

Main Concepts. The given metric \(g_{ab}\) is a symmetric, covariant tensor with component functions \(g_{ab} : U \to \mathbb{R}\), for \(1 \leq \alpha, \beta \leq d\), which we assume are at least \(C^1\), and is uniformly positive definite.

We write \(g \equiv \det g_{ab}\) and the inverse metric tensor \(g^{ab}\) is contravariant with components denoted \(g^{ab}\), where \(g_{\alpha\beta}g^{\alpha\beta} = \delta_\alpha^\beta\). Note that \(v^a\) may be converted to \(v_\alpha\) via \(v_\alpha = g_{\alpha\beta}v^\beta\); similarly, \(w_\beta\) may be converted to \(w^\alpha\) by \(w^\alpha = g^{\alpha\beta}w_\beta\). When convenient, we write \(g_{ab} \equiv g = [g_{\alpha\beta}]_{\alpha, \beta=1}^2\) and \(g^{ab} \equiv g^{-1} = [g^{\alpha\beta}]_{\alpha, \beta=1}^2\) in standard matrix notation for the metric and inverse metric, respectively.

Let \(T_2 = T_2(\Gamma)\) \((T^2 = T^2(\Gamma))\) be the set of covariant (contravariant) 2-tensors on \(\Gamma\). Moreover, \(S_2 \subset T_2\) and \(S^2 \subset T^2\) are subsets of symmetric tensors; so then \(g_{ab} \in S_2\) and \(g^{ab} \in S^2\).

The Christoffel symbols \(\Gamma^\gamma_{\alpha\beta}\) (of the second kind) are defined by

\[
\Gamma^\gamma_{\alpha\beta} := \frac{1}{2}g^{\mu\gamma}(\partial_\alpha g_{\beta\mu} + \partial_\beta g_{\mu\alpha} - \partial_\mu g_{\alpha\beta}), \quad 1 \leq \alpha, \beta, \gamma \leq 2, \tag{A.1}
\]

where \(\Gamma^\gamma_{\alpha\beta} = \Gamma^\gamma_{\beta\alpha}\) do Carmo (1992, 1976). With this, we recall the definition of covariant (contravariant) derivatives, denoted \(\nabla_\alpha\) \((\nabla^\alpha)\), where \(f\) is a scalar, \(v_\beta\) is a covariant vector, and \(v^\alpha\) is a contravariant vector:

\[
\nabla_\alpha f = \partial_\alpha f, \quad \nabla_\alpha \nabla_\beta f = \partial_\alpha \partial_\beta f - (\partial_\gamma f)\Gamma^\gamma_{\alpha\beta},
\]

\[
\nabla_\alpha v_\beta = \partial_\alpha v_\beta - v_\gamma \Gamma^\gamma_{\alpha\beta}, \quad \nabla_\alpha v^\gamma = \partial_\alpha v^\gamma + v^\mu \Gamma^\gamma_{\alpha\mu}, \quad \nabla_\alpha v^\alpha = (\sqrt{g})^{-1}\partial_\alpha (v^\alpha \sqrt{g}). \tag{A.2}
\]

The metric satisfies \(\nabla_\gamma g_{ab} = 0, \nabla_\gamma g^{ab} = 0, \nabla_\gamma g = 0\), for \(1 \leq \alpha, \beta, \gamma \leq 2\), do Carmo (1992).

Let \(n_\alpha\) be the conormal vector of \(\partial U\), and \(n^\mu = g^{\mu\gamma}n_\gamma\). Viewing \(n_\alpha\) as a “vector” in \(\mathbb{R}^d\), it has unit length under the \(\mathbb{R}^d\) Euclidean metric. If \(d = 2\), let \(t^a\) be the oriented (contravariant) tangent vector of
\[ \partial U, \text{ which has unit length in the Euclidean metric and satisfies } n_{\alpha} t^\alpha = 0. \] Moreover, \( g = t^\mu t_\mu / (n^\mu n_\mu) \), which implies that \( ds(g) := \sqrt{t^\mu t_\mu} \, dl \) for \( d = 2 \), and we have the following "orthogonal" decomposition

\[ \delta^a_\beta = \frac{n^{\alpha} n_\beta}{n^\mu n_\mu} + \frac{t^{\alpha} t_\beta}{t^\mu t_\mu}. \quad (A.3) \]

### A.2 Extrinsic Differential Geometry

Suppose that the manifold \( \Gamma \) is embedded in \( \mathbb{R}^n \), with \( n \geq d \), and that it is represented by a family of charts \( \{(U_i, \chi_i)\} \), where a single chart consists of a pair \( (U, \chi) \), with \( U \subset \mathbb{R}^d \) (reference domain) and \( \chi : U \to \mathbb{R}^n \) do Carmo (1992). For simplicity of exposition, assume there is only one chart \( (U, \chi) \), where \( \Gamma = \chi(U) \). We refer to variables in \( \mathbb{R}^n \) as extrinsic quantities.

**Tensor Index Notation.** We use lower-case *Latin* letters starting with \( i \) (i.e. \( i, j, k, l \), etc.), which take values in \( \{1, 2, \ldots, n\} \), when referring to components of extrinsic (ambient space) quantities. For example, \( \chi = (\chi^1, \ldots, \chi^n)^T \in \mathbb{R}^n \), and \( \chi^i : U \to \mathbb{R} \) for each \( i \in \{1, 2, \ldots, n\} \). A point \( x \in \mathbb{R}^n \) has its \( j \)-th coordinate denoted by \( x^j \). Moreover, \( \partial_\chi \) is the partial derivative with respect to coordinate \( x^\chi \). Repeated indices are summed over. We typically bold-face extrinsic vectors and tensors, e.g. let \( w \) be a (covariant) \( 2 \)-tensor in \( \mathbb{R}^n \) with components \( w_{ij} \) for \( i, j \in \{1, 2, \ldots, n\} \). The canonical (orthonormal) basis in \( \mathbb{R}^n \), is denoted by \( \{a_k\}_{k=1}^n \), where \( a_k = (1, 0, \ldots, 0)^T \) (column vector), etc. With the Kronecker delta \( \delta^i_j \), we have the dual basis \( \{a^i\} \) of \( \{a_k\} \) by the formula \( a^i \cdot a^j = \delta^j_i \).

**Differential Geometry in the Ambient Space.** The tangent space \( T_{\chi}(\Gamma) \), at a point \( x \in \Gamma \), is a subspace of \( \mathbb{R}^n \) spanned by \( \{e_1, e_2, \ldots, e_d\} \) (the covariant basis) where

\[ e_\alpha = \partial_\chi \chi(u^\alpha), \quad 1 \leq \alpha \leq d, \quad \text{where } u^\alpha = (u^1, \ldots, u^d) = \chi^{-1}(x). \quad (A.4) \]

In this case, the metric tensor \( g_{ab} \) is given by \( g_{\alpha\beta} = e_\alpha \cdot e_\beta \), for \( 1 \leq \alpha, \beta \leq d \). The contravariant tangent basis is given by \( \{e^1, e^2, \ldots, e^d\} \), where \( e^\beta = e_\alpha g^{\alpha\beta} = (\partial_\chi \chi)g^{\alpha\beta} \) Ciarlet (2013). Sometimes, we express \( g_{ab} \equiv g = J^T J \), where \( J = [e_1, \ldots, e_d] \) is an \( n \times d \) matrix.

Given a vector \( v \in \mathbb{R}^n \), it is in the tangent space \( T_{\chi}(\Gamma) \) if there exists a (contravariant) vector \( v^a \) such that \( v(x) = v^a e_\alpha \circ \chi^{-1}(x) \). Alternatively, one can write it in terms of a co-vector \( v^a \) and the contravariant basis: \( v(x) = v^\alpha e^\alpha \circ \chi^{-1}(x) \). Moreover, any covariant (contravariant) vector \( v_\alpha \) (\( v^a \)) has a corresponding extrinsic version given by \( v = v_\alpha e_\alpha \) (\( v = v^a e^a \)). We define the tangent bundle:

\[ T(\Gamma) = \{(x, v) \mid x \in \Gamma, v(x) \in T_{\chi}(\Gamma)\}, \quad (A.5) \]

thus, we say \( v \in T(\Gamma) \) if \( v(x) \in T_{\chi}(\Gamma) \) for every \( x \in \Gamma \); in this case, we write \( v : \Gamma \to T(\Gamma) \). In addition, let \( \mathbb{R}^{n \times n} \) be the space of (extrinsic) \( 2 \)-tensors, and define the subset of tensors on the tangent bundle of \( \Gamma \):

\[ T = T(\Gamma) := \{w : \Gamma \to \mathbb{R}^{n \times n} \mid w = w^{\alpha\beta} e_\alpha \otimes e_\beta \}, \quad \text{for some } w^{\alpha\beta} \in T^2(\Gamma) \}, \quad (A.6) \]

and define the set of symmetric tensors on the tangent bundle of \( \Gamma \):

\[ S = S(\Gamma) := \{w \in T(\Gamma) \mid w = w^{\alpha\beta} e_\alpha \otimes e_\beta \}, \quad \text{for some } w^{\alpha\beta} \in S^2(\Gamma) \}. \quad (A.7) \]
Next, we introduce extrinsic differential operators via their intrinsic counterpart, starting with the surface gradient \( \nabla_\Gamma f : \Gamma \to T(\Gamma) \) defined in local coordinates by
\[
(\nabla_\Gamma f) \circ \chi = (\nabla \alpha f) g^{\alpha \beta} e^\beta = \partial_\alpha (f \circ \chi) g^{\alpha \beta} (\partial_\beta \chi)^T \equiv \nabla (f \circ \chi) g^{-1} J^T, \tag{A.8}
\]
for any differentiable function \( f : \Gamma \to \mathbb{R} \). The (extrinsic) surface gradient of a tangential vector field \( v \in T(\Gamma) \) is \( \nabla_\Gamma v \circ \chi := e_\mu g^{\gamma \alpha}(\nabla_\beta v_\gamma) g^{\beta \mu} e^\gamma = e_\mu g^{\gamma \alpha}(\partial_\beta v_\gamma - v_\alpha \Gamma^\gamma_{\alpha \beta}) g^{\beta \mu} e^\gamma \), so then \( \nabla_\Gamma v \in T \). Moreover, \( (\nabla_\Gamma \cdot v) \circ \chi := \text{tr}(\nabla_\Gamma v \circ \chi) = g^{\gamma \alpha}(\nabla_\beta v_\gamma) g^{\beta \mu} e_\mu \cdot e_\gamma = \nabla_\beta (g^{\gamma \alpha} v_\gamma) g^{\beta \mu} g_{\mu \gamma} = \delta_\gamma^\beta (\nabla_\beta v_\gamma) = \nabla_\beta v_\gamma \). The (covariant) surface Hessian, an element of \( S \), is given by
\[
(\nabla \nabla f) \circ \chi := e_\mu g^{\alpha \beta}[\nabla_\alpha \nabla_\beta f] g^{\beta \rho} e^\rho = e_\mu g^{\alpha \beta}[\partial_\alpha \partial_\beta (f \circ \chi) - \partial_\beta (f \circ \chi) \Gamma^\gamma_{\alpha \beta}] g^{\gamma \rho} e^\rho. \tag{A.9}
\]

**Special Case of a Surface.** Suppose \( d = 2 \) and \( n = 3 \). Let \( Y = \chi(Y) \), where \( Y \subset U \), be a 1-D curve embedded in \( \Gamma \), and let \( t \) be the unit tangent vector of \( Y \) and let \( n \) be the conormal vector of \( Y \) (\( t \) and \( n \) are both tangent to \( \Gamma \)). In local coordinates, we have
\[
I \circ \chi \big|_Y = \frac{t^\alpha e_\alpha}{|t^\alpha e_\alpha|}, \quad n \circ \chi \big|_Y = \frac{n_\beta e_\beta}{|n_\beta e_\beta|}, \tag{A.10}
\]
where \( |a| \) denotes the Euclidean length of the vector \( a \in \mathbb{R}^3 \), \( t^\alpha \) is the (contravariant) tangent vector of \( Y \), and \( n_\beta \) is the (covariant) normal vector of \( Y \). Furthermore, let \( \mathbf{v} : \Gamma \to \mathbb{R}^3 \) be the surface unit normal vector of \( \Gamma \), which satisfies \( n = t \times \mathbf{v} \) Walker (2015) on \( \partial \Gamma \). With the ambient space \( \mathbb{R}^3 \) available, the tangent space projection \( P : \mathbb{R}^3 \to \mathbb{R}^3 \), defined on \( \Gamma \), is given by
\[
P = I - \mathbf{v} \otimes \mathbf{v} = t \otimes t + n \otimes n, \tag{A.11}
\]
and note that (in local coordinates) \( J g^{-1} J^T = P \circ \chi \) Walker (2015).

From Definition 4.6, we have the identity:
\[
n^T \phi n \circ \chi \big|_Y = \frac{1}{g \sqrt{n_\mu n^\mu}} \left( n_\beta e^\beta \right)^T e_\alpha \phi^\alpha e_\beta \left( n_\alpha e_\alpha \right) \sqrt{n_\mu n^\mu} = \frac{1}{t^\mu t_\mu n_\alpha \phi^\alpha n_\beta = \frac{1}{|t^\mu e_\mu|^2} n_\alpha \phi^\alpha n_\beta}, \tag{A.12}
\]
where we used \( g = t^\mu t_\mu / (n^\mu n_\mu) \).

### A.3 Parametrization Via Curved Element Map

Recall \( F^I_T : T^I \to T^I \) from Section 4.1. It is useful to consider this map as a parametrization of \( T^I \) in the following sense. Apply a rigid rotation of coordinates \( \mathbf{x} \) to \( \mathbf{x'} \) so that \( T^I \to T^{I'} \) (for any \( s \)) and \( T^{I'} \subset \mathbb{R}^2 \). In the rotated coordinates, we view \( F^I_T \) as a function of two variables, so that \( T^{I'} \cdot \mathbf{F}^I_T \) is a local chart for \( T^{I'} \). Next, let \( J' = [\partial_1 F^I_T, \partial_2 F^I_T] \) be the \( 3 \times 2 \) Jacobian matrix with induced metric \( g' = (J')^T J' \). In addition, define the \( 3 \times 2 \) matrix \( \mathbf{P} = [a_1, a_2, a_3] \), where \( \{a_1, a_2, a_3\} \) are the canonical basis vectors of \( \mathbb{R}^3 \), \( (\mathbf{P}^I)^T \mathbf{P}^I = I_3 \), and \( \mathbf{P}^I = (\mathbf{P}^I)^T = \mathbf{P}' = I_3 - \mathbf{v}' \otimes \mathbf{v}' \), where \( \mathbf{v}' = a_3 \) is the unit normal of \( T^{I'} \).

All results derived in the rotated coordinates can be mapped back to the original coordinates. For example, let \( \mathbf{P} = [b_1, b_2] \), where \( b_1, b_2 \) are any two orthogonal unit vectors in \( \mathbb{R}^3 \) pointing in the plane.
of $T^1$, and note that $\mathbf{P}_*^T \mathbf{P}_* = \mathbf{I}_2$, and $\mathbf{P}_*^T = \mathbf{P} := \mathbf{I}_3 - \mathbf{V} \otimes \mathbf{V}$ (see (A.11)), where $\mathbf{V} = b_1 \times b_2$ is the unit normal of $T^1$. Then, $\mathbf{J} = (\nabla_{T^1} \mathbf{F}_T^i) \mathbf{P}_*$, $\mathbf{g} = \mathbf{J}^T \mathbf{J}$, and by (4.3),

$$|\mathbf{J} - \mathbf{P}_*| = O(h), \quad \mathbf{g} = \mathbf{P}_*^T \mathbf{P} \mathbf{P}_* + O(h) = \mathbf{I}_2 + O(h),$$

(A.13)

so $\mathbf{g}$ is invertible for $h$ sufficiently small. Note that, in terms of $\mathbf{F}_T^i$, the surface gradient (A.8) of $f : T^1 \to \mathbb{R}$ can be written as $(\nabla_{T^1} f) \circ \mathbf{F}_T^i = (\nabla_{T^1} f) \mathbf{P}_* \mathbf{g}^{-1} \mathbf{J}^T$, where $\mathbf{f} := f \circ \mathbf{F}_T^i$.

A.4 Technical Estimates

Be elementary geometry, we have the following estimate.

**Lemma A.1** Let $\mathbf{a}, \mathbf{b}$ be unit vectors, with respect to the Euclidean norm, in $\mathbb{R}^n$. If $|\mathbf{a} - \mathbf{b}| = \gamma \leq \sqrt{2}$, then $|\mathbf{a} - \mathbf{b}| \leq (3/4) \gamma^2$.

**Lemma A.2** Let $T \in \mathcal{T}_h$ with unit conormal $\mathbf{n}$, and unit tangent $\mathbf{t}$, vectors (in $\mathbb{R}^3$) defined on $\partial T$. Suppose $m > l \geq 1$ and consider the corresponding elements $T^m \in \mathcal{T}_h^m$, $T^l \in \mathcal{T}_h^l$, and $T^1 \in \mathcal{T}_h^1$, i.e. $T^m = \mathbf{F}_T^m (T^1)$, for any $m \geq s \geq 1$ or $s = \infty$ (recall the discussion in Section 4.1). Let $\mathbf{J} = (\nabla_{T^1} \mathbf{F}_T^i) \mathbf{P}_*$, $\mathbf{g} = \mathbf{J}^T \mathbf{J}$ and recall (4.4) and the notation introduced there. Then, on $T^1$, the following holds

$$\left[(\mathbf{n} \circ \mathbf{F}_T^m) - (\mathbf{n} \circ \mathbf{F}_T^l)\right] \cdot (\mathbf{n} \circ \mathbf{F}_T^m) = O(h^{2l}),$$

$$\left[(\mathbf{n} \circ \mathbf{F}_T^m) - (\mathbf{n} \circ \mathbf{F}_T^l)\right]^T (\mathbf{P} \circ \mathbf{F}_T^m) = \beta \mathbf{I}^T \mathbf{P} + O(h^{2l}) = O(h^l),$$

$$\mathbf{n}^T (\mathbf{J} \mathbf{g}^{-1} - \mathbf{J} \mathbf{g}^{-1}) \mathbf{P}_* = -[\mathbf{n} \cdot \nabla_{T^1} (\mathbf{F}_T^m \mathbf{F}_T^l)]^T \overline{\mathbf{P}} + O(h^{l+1}) = O(h^l),$$

(A.14)

where $\beta = |(\mathbf{i} - \mathbf{i}) \times \mathbf{V}| \cdot \mathbf{i}$, $|\beta| = O(h^l)$, and $\beta$ is continuous across edges of the mesh. Furthermore,

$$\left[(\mathbf{n} \circ \mathbf{F}_T^m)^T \mathbf{J} \mathbf{g}^{-1} \mathbf{P}_* \right] ^T - \left[(\mathbf{n} \circ \mathbf{F}_T^l)^T \mathbf{J} \mathbf{g}^{-1} \mathbf{P}_* \right] ^T = \beta \mathbf{I}^T \mathbf{P} - [\mathbf{n} \cdot \nabla_{T^1} (\mathbf{F}_T^m \mathbf{F}_T^l)]^T \overline{\mathbf{P}} + O(h^{l+1}) = O(h^l),$$

$$\mathbf{n}^T (\mathbf{J} \mathbf{g}^{-1} \mathbf{P}_* - \mathbf{n}) = O(h^l)$$

where $\beta = |(\mathbf{i} - \mathbf{i}) \times \mathbf{V}| \cdot \mathbf{i}$, $|\beta| = O(h^l)$, and $\beta$ is continuous across element boundaries.

**Proof.** Referring to Section A.3, we rotate coordinates so that $T^1 \subset \mathbb{R}^2$ and we simplify notation by dropping $T$. We also abuse notation and write $\tilde{\mathbf{n}} \equiv \mathbf{n} \circ \mathbf{F}_T^m$ and $\tilde{\mathbf{n}} \equiv \mathbf{n} \circ \mathbf{F}_T^l$. From (A.10), we have that

$$\tilde{\mathbf{n}} = \mathbf{J} \mathbf{g}^{-1} \mathbf{P}_* \mathbf{n} / |\mathbf{J} \mathbf{g}^{-1} \mathbf{P}_* \mathbf{n}|$$

(notice that $\tilde{\mathbf{n}} \cdot \mathbf{a}_3 = 0$).

The first line of (A.14) follows immediately from (4.4) and Lemma A.1. Next, note that $\mathbf{J} \mathbf{g}^{-1} \mathbf{J} = \mathbf{P} \circ \mathbf{F}_T^m \equiv \mathbf{P} = \mathbf{I}_3 - \mathbf{V} \otimes \mathbf{V}$ (see (A.11)), i.e. the tangent space projection onto $T^m$, where $\mathbf{V} = \mathbf{b}_1 \times \mathbf{b}_2$ is the unit normal vector of $T^m$. Estimating $\mathbf{w}_1^T := (\tilde{\mathbf{n}} - \mathbf{n})^T \mathbf{P}$ gives $\mathbf{w}_1^T = O(h^{2l}) + (\tilde{\mathbf{n}} - \mathbf{n})^T \mathbf{n}^T \mathbf{P} + [(\tilde{\mathbf{n}} - \mathbf{n}) \cdot \mathbf{i}] \mathbf{i}^T \mathbf{P}$, where we used the first line of (A.14). Moreover,

$$\mathbf{n} - \mathbf{J} \mathbf{g}^{-1} \mathbf{P}_* \mathbf{P} + O(h^{2l}) = \mathbf{J} \mathbf{g}^{-1} \mathbf{P}_* \mathbf{n} / |\mathbf{J} \mathbf{g}^{-1} \mathbf{P}_* \mathbf{n}|$$

(notice that $\tilde{\mathbf{n}} \cdot \mathbf{a}_3 = 0$).

where $\beta := |(\mathbf{i} - \mathbf{i}) \times \mathbf{V}| \cdot \mathbf{i}$ (and $\beta = O(h^l)$), and we used (4.4); hence, $\mathbf{w}_1^T = \beta \mathbf{I}^T \mathbf{P} + O(h^{2l}) = \beta \mathbf{I}^T \mathbf{P} + O(h^{l+1})$ so we obtain the second line of (A.14). Also note that $\beta$ is continuous across element boundaries.
Next, let $w^T_2 := n^T (J g^{-1} - \hat{J} g^{-1}) \hat{P} \hat{z}^T$ and estimate

$$w^T_2 = n^T (J g^{-1} - \hat{J} g^{-1}) \hat{P} \hat{z}^T - n^T (J g^{-1} - \hat{J} g^{-1}) \hat{P} \hat{z}^T$$

$$= n^T \hat{P} (\hat{P}^T - \hat{P}^T) J g^{-1} \hat{P} \hat{z}^T - n^T \hat{P} (\hat{P}^T - \hat{P}^T) J g^{-1} \hat{P} \hat{z}^T$$

$$= n^T \hat{P} (\hat{P}^T - \hat{P}^T) J g^{-1} \hat{P} \hat{z}^T - n^T \hat{P} (\hat{P}^T - \hat{P}^T) J g^{-1} \hat{P} \hat{z}^T$$

$$+ n^T \hat{P} (\hat{P}^T - \hat{P}^T) J g^{-1} \hat{P} \hat{z}^T$$

$$= n^T \hat{P} (\hat{J} \hat{P}^T - \hat{J} \hat{P}^T) J g^{-1} \hat{P} \hat{z}^T = O(h^2),$$

where we used (4.3) and (A.13). Again referring to Section A.3, we find that

$$w^T_2 = \hat{n}^T [\nabla_{P^1} (F^m - F^m)]^T \hat{P} + O(h^2),$$

so we obtain the third line of (A.14).

As for (A.15), let $z^T = n^T J g^{-1} \hat{P} \hat{z}^T - n^T J g^{-1} \hat{P} \hat{z}^T$, where $z \in \mathbb{R}^3$, and expand:

$$z^T = (n - n)^T J g^{-1} \hat{P} \hat{z}^T + n^T (J g^{-1} - \hat{J} g^{-1}) \hat{P} \hat{z}^T$$

$$= (n - n)^T J g^{-1} \hat{P} \hat{z}^T + n^T (J g^{-1} - \hat{J} g^{-1}) \hat{P} \hat{z}^T$$

$$+ (n - n)^T (J g^{-1} - \hat{J} g^{-1}) \hat{P} \hat{z}^T + n^T (J g^{-1} - \hat{J} g^{-1}) \hat{P} \hat{z}^T =: w^T_1 \hat{P} + z^T_1 + z^T_2 + z^T_3.$$

Since $|z_1| = O(h^2) = |z_2|$, combining with the above results yields the first line of (A.15).

Now set $l = 1$, so that the first line of (A.15) simplifies to

$$\hat{n}^T J g^{-1} \hat{P} \hat{z}^T - \hat{n}^T \hat{P} \hat{z}^T = \beta \hat{n}^T \hat{P} - [n \cdot \nabla_{P^1} (F^m - F^m)]^T \hat{P} + O(h^2),$$

and note that $\hat{n}^T \hat{P} \hat{z}^T = \hat{n}^T$. Since $|\beta| = O(h)$, and $|\nabla_{P^1} (F^m - F^m)| = O(h)$, we get the second line of (A.15).

\[\square\]

### A.5 Discrete Inf-Sup Condition

The discrete inf-sup condition for the HHJ method was proved for flat polygonal domains in (Blum & Rannacher, 1990, pf. of Lem. 5.1). Their proof readily extends to piecewise linear surface triangulations, mutatis mutandis (which we omit). The final result we need is as follows.

**Lemma A.3** Assume $\Gamma^1$ is a piecewise linear triangulation in $\mathbb{R}^3$ that interpolates a surface $\Gamma$ satisfying the conditions in Section 3.1. Then,

$$\sup_{\varphi \in W_h^1} \frac{|\beta_h^1(\varphi, v)|}{\|\varphi\|_0h^1} \geq C_0\|v\|_{2,h^1}, \quad \forall v \in W_h^1, \forall h > 0,$$

holds for any degree $r \geq 0$, where $C_0 > 0$ is independent of $h$.
